Abstract

The main feature of Red Hat Identity Management (IdM) is the management of users, groups, hosts, and access control rules, such as host-based access control (HBAC) and role-based access control (RBAC). You can configure them by using the command line, the IdM Web UI, and Ansible Playbooks. The management tasks include configuring Kerberos policies and security, automating group memberships, and delegating permissions.

Table of Contents

PROVIDING FEEDBACK ON RED HAT DOCUMENTATION	. 11
CHAPTER 1. MANAGING USER ACCOUNTS USING THE COMMAND LINE	12
1.1. USER LIFE CYCLE	12
1.2. ADDING USERS USING THE COMMAND LINE	13
1.3. ACTIVATING USERS USING THE COMMAND LINE	15
1.4. PRESERVING USERS USING THE COMMAND LINE	16
1.5. DELETING USERS USING THE COMMAND LINE	16
1.6. RESTORING USERS USING THE COMMAND LINE	17
1.7. ADDITIONAL RESOURCES	18
CHAPTER 2. MANAGING USER ACCOUNTS USING THE IDM WEB UI	19
2.1. USER LIFE CYCLE	19
2.2. ADDING USERS IN THE WEB UI	19
2.3. ACTIVATING STAGE USERS IN THE IDM WEB UI	20
2.4. DISABLING USER ACCOUNTS IN THE WEB UI	21
2.5. ENABLING USER ACCOUNTS IN THE WEB UI	22
2.6. PRESERVING ACTIVE USERS IN THE IDM WEB UI	22
2.7. RESTORING USERS IN THE IDM WEB UI	23
2.8. DELETING USERS IN THE IDM WEB UI	23
CHAPTER 3. MANAGING USER ACCOUNTS USING ANSIBLE PLAYBOOKS	25
3.1. USER LIFE CYCLE	25
3.2. ENSURING THE PRESENCE OF AN IDM USER USING AN ANSIBLE PLAYBOOK	25
3.3. ENSURING THE PRESENCE OF MULTIPLE IDM USERS USING ANSIBLE PLAYBOOKS	27
3.4. ENSURING THE PRESENCE OF MULTIPLE IDM USERS FROM A JSON FILE USING ANSIBLE	29
PLAYBOOKS 3.5. ENSURING THE ABSENCE OF USERS USING ANSIBLE PLAYBOOKS	30
CHAPTER 4. MODIFYING USER AND GROUP ATTRIBUTES IN IDM	33
	33
4.1. THE DEFAULT IDM USER ATTRIBUTES 4.2. CONSIDERATIONS IN CHANGING THE DEFAULT USER AND GROUP SCHEMA	35
4.2. CONSIDERATIONS IN CHANGING THE DEFAULT USER AND GROUP SCHEMA 4.3. MODIFYING USER OBJECT CLASSES IN THE IDM WEB UI	35 36
4.4. MODIFYING USER OBJECT CLASSES IN THE IDM CLI	37
4.5. MODIFYING GROUP OBJECT CLASSES IN THE IDM WEB UI	37
4.6. MODIFYING GROUP OBJECT CLASSES IN THE IDM CLI	39
4.7. DEFAULT USER AND GROUP ATTRIBUTES IN IDM	39
4.8. VIEWING AND MODIFYING USER AND GROUP CONFIGURATION IN THE IDM WEB UI	41
4.9. VIEWING AND MODIFYING USER AND GROUP CONFIGURATION IN THE IDM CLI	42
4.10. ADDITIONAL RESOURCES	42
CHAPTER 5. MANAGING USER PASSWORDS IN IDM	43
5.1. WHO CAN CHANGE IDM USER PASSWORDS AND HOW	43
5.2. CHANGING YOUR USER PASSWORD IN THE IDM WEB UI	43
5.3. RESETTING ANOTHER USER'S PASSWORD IN THE IDM WEB UI	43
5.4. RESETTING THE DIRECTORY MANAGER USER PASSWORD	44
5.5. CHANGING YOUR USER PASSWORD OR RESETTING ANOTHER USER'S PASSWORD IN IDM CLI	44
5.6. ENABLING PASSWORD RESET IN IDM WITHOUT PROMPTING THE USER FOR A PASSWORD CHANGI	E
AT THE NEXT LOGIN	45
5.7. CHECKING IF AN IDM USER'S ACCOUNT IS LOCKED	46
5.8. UNLOCKING USER ACCOUNTS AFTER PASSWORD FAILURES IN IDM	47
5.9. ENABLING THE TRACKING OF LAST SUCCESSFUL KERBEROS AUTHENTICATION FOR USERS IN IDN	1 12

CHAPTER 6. DEFINING IDM PASSWORD POLICIES	49
6.1. WHAT IS A PASSWORD POLICY	49
6.2. PASSWORD POLICIES IN IDM	49
6.3. PASSWORD POLICY PRIORITIES IN IDM	51
6.4. ADDING A NEW PASSWORD POLICY IN IDM USING THE WEBUI OR THE CLI	51
6.4.1. Adding a new password policy in the IdM WebUI	51
6.4.2. Adding a new password policy in the IdM CLI	52
6.5. ADDITIONAL PASSWORD POLICY OPTIONS IN IDM	52
6.6. APPLYING ADDITIONAL PASSWORD POLICY OPTIONS TO AN IDM GROUP	53
CHAPTER 7. MANAGING EXPIRING PASSWORD NOTIFICATIONS	57
7.1. WHAT IS THE EXPIRING PASSWORD NOTIFICATION TOOL	57
7.2. INSTALLING THE EXPIRING PASSWORD NOTIFICATION TOOL	57
7.3. RUNNING THE EPN TOOL TO SEND EMAILS TO USERS WHOSE PASSWORDS ARE EXPIRING	57
7.4. ENABLING THE IPA-EPN.TIMER TO SEND AN EMAIL TO ALL USERS WHOSE PASSWORDS ARE EXPIRING	60
7.5. MODIFYING THE EXPIRING PASSWORD NOTIFICATION EMAIL TEMPLATE	61
CHAPTER 8. GRANTING SUDO ACCESS TO AN IDM USER ON AN IDM CLIENT 8.1. SUDO ACCESS ON AN IDM CLIENT	62
8.2. GRANTING SUDO ACCESS TO AN IDM USER ON AN IDM CLIENT USING THE CLI	62
8.3. GRANTING SUDO ACCESS TO AN AD USER ON AN IDM CLIENT USING THE CLI	65
8.4. GRANTING SUDO ACCESS TO AN IDM USER ON AN IDM CLIENT USING THE IDM WEB UI	68
8.5. CREATING A SUDO RULE ON THE CLI THAT RUNS A COMMAND AS A SERVICE ACCOUNT ON AN ID	
CLIENT	71
8.6. CREATING A SUDO RULE IN THE IDM WEBUI THAT RUNS A COMMAND AS A SERVICE ACCOUNT ON	
IDM CLIENT	74
8.7. ENABLING GSSAPI AUTHENTICATION FOR SUDO ON AN IDM CLIENT	79
8.8. ENABLING GSSAPI AUTHENTICATION AND ENFORCING KERBEROS AUTHENTICATION INDICATOR FOR SUDO ON AN IDM CLIENT	S 81
8.9. SSSD OPTIONS CONTROLLING GSSAPI AUTHENTICATION FOR PAM SERVICES	83
8.10. TROUBLESHOOTING GSSAPI AUTHENTICATION FOR SUDO	84
8.11. ADDITIONAL RESOURCES	86
CHAPTER 9. USING LDAPMODIFY TO MANAGE IDM USERS EXTERNALLY	
9.1. TEMPLATES FOR MANAGING IDM USER ACCOUNTS EXTERNALLY	87
9.2. TEMPLATES FOR MANAGING IDM GROUP ACCOUNTS EXTERNALLY	89
9.3. USING LDAPMODIFY COMMAND INTERACTIVELY	90
9.4. PRESERVING AN IDM USER WITH LDAPMODIFY	91
CHAPTER 10. SEARCHING IDM ENTRIES USING THE LDAPSEARCH COMMAND	
10.1. USING THE LDAPSEARCH COMMAND	93
10.2. USING THE LDAPSEARCH FILTERS	94
10.3. ADDITIONAL RESOURCES	96
CHAPTER 11. CONFIGURING IDM FOR EXTERNAL PROVISIONING OF USERS	97
11.1. PREPARING IDM ACCOUNTS FOR AUTOMATIC ACTIVATION OF STAGE USER ACCOUNTS	97
11.2. CONFIGURING AUTOMATIC ACTIVATION OF IDM STAGE USER ACCOUNTS	99
11.3. ADDING AN IDM STAGE USER DEFINED IN AN LDIF FILE	101
11.4. ADDING AN IDM STAGE USER DIRECTLY FROM THE CLI USING LDAPMODIFY	102
11.5. ADDITIONAL RESOURCES	104
CHAPTER 12. MANAGING KERBEROS PRINCIPAL ALIASES FOR USERS, HOSTS, AND SERVICES	105
12.1. ADDING A KERBEROS PRINCIPAL ALIAS	105
12.2. REMOVING A KERBEROS PRINCIPAL ALIAS	105

12.3. ADDING A KERBEROS ENTERPRISE PRINCIPAL ALIAS	106
12.4. REMOVING A KERBEROS ENTERPRISE PRINCIPAL ALIAS	107
CHAPTER 13. STRENGTHENING KERBEROS SECURITY WITH PAC INFORMATION	108
13.1. PRIVILEGE ATTRIBUTE CERTIFICATE (PAC) USE IN IDM	108
13.2. ENABLING SECURITY IDENTIFIERS (SIDS) IN IDM	108
CHAPTER 14. MANAGING KERBEROS TICKET POLICIES	110
14.1. THE ROLE OF THE IDM KDC	110
14.2. IDM KERBEROS TICKET POLICY TYPES	111
14.3. KERBEROS AUTHENTICATION INDICATORS	111
14.4. ENFORCING AUTHENTICATION INDICATORS FOR AN IDM SERVICE	112
14.4.1. Creating an IdM service entry and its Kerberos keytab	113
14.4.2. Associating authentication indicators with an IdM service using IdM CLI	114
14.4.3. Associating authentication indicators with an IdM service using IdM Web UI	116
14.4.4. Retrieving a Kerberos service ticket for an IdM service	117
14.4.5. Additional resources	118
14.5. CONFIGURING THE GLOBAL TICKET LIFECYCLE POLICY	118
14.6. CONFIGURING GLOBAL TICKET POLICIES PER AUTHENTICATION INDICATOR	119
14.7. CONFIGURING THE DEFAULT TICKET POLICY FOR A USER	119
14.8. CONFIGURING INDIVIDUAL AUTHENTICATION INDICATOR TICKET POLICIES FOR A USER	120
14.9. AUTHENTICATION INDICATOR OPTIONS FOR THE KRBTPOLICY-MOD COMMAND	121
CHAPTER 15. KERBEROS PKINIT AUTHENTICATION IN IDM	122
15.1. DEFAULT PKINIT CONFIGURATION	122
15.2. DISPLAYING THE CURRENT PKINIT CONFIGURATION	122
15.3. CONFIGURING PKINIT IN IDM	123
15.4. ADDITIONAL RESOURCES	124
CHAPTER 16. MAINTAINING IDM KERBEROS KEYTAB FILES	125
16.1. HOW IDENTITY MANAGEMENT USES KERBEROS KEYTAB FILES	125
16.2. VERIFYING THAT KERBEROS KEYTAB FILES ARE IN SYNC WITH THE IDM DATABASE	125
16.3. LIST OF IDM KERBEROS KEYTAB FILES AND THEIR CONTENTS	127
16.4. VIEWING THE ENCRYPTION TYPE OF YOUR IDM MASTER KEY	128
CHAPTER 17. ENABLING PASSKEY AUTHENTICATION IN IDM ENVIRONMENT	129
17.1. PREREQUISITES	129
17.2. REGISTERING A PASSKEY DEVICE	129
17.3. AUTHENTICATION POLICIES	131
17.4. RETRIEVING AN IDM TICKET-GRANTING TICKET AS A PASSKEY USER	131
CHAPTER 18. USING THE KDC PROXY IN IDM	133
18.1. CONFIGURING AN IDM CLIENT TO USE KKDCP	133
18.2. VERIFYING THAT KKDCP IS ENABLED ON AN IDM SERVER	133
18.3. DISABLING KKDCP ON AN IDM SERVER	134
18.4. RE-ENABLING KKDCP ON AN IDM SERVER	134
18.5. CONFIGURING THE KKDCP SERVER I	135
18.6. CONFIGURING THE KKDCP SERVER II	136
CHAPTER 19. MANAGING SELF-SERVICE RULES IN IDM USING THE CLI	137
19.1. SELF-SERVICE ACCESS CONTROL IN IDM	137
19.2. CREATING SELF-SERVICE RULES USING THE CLI	137
19.3. EDITING SELF-SERVICE RULES USING THE CLI	138

PROVIDING FEEDBACK ON RED HAT DOCUMENTATION

We appreciate your feedback on our documentation. Let us know how we can improve it.

Submitting feedback through Jira (account required)

- 1. Log in to the Jira website.
- 2. Click **Create** in the top navigation bar
- 3. Enter a descriptive title in the **Summary** field.
- 4. Enter your suggestion for improvement in the **Description** field. Include links to the relevant parts of the documentation.
- 5. Click **Create** at the bottom of the dialogue.

CHAPTER 1. MANAGING USER ACCOUNTS USING THE COMMAND LINE

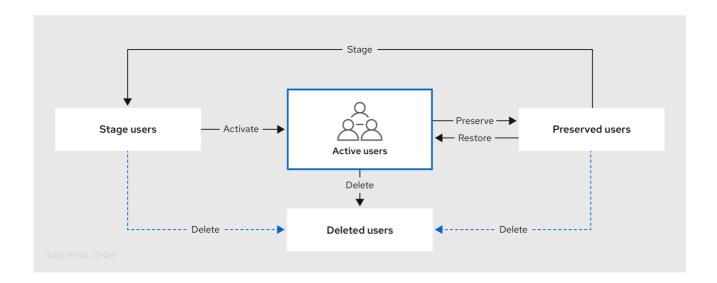

There are several stages in the user life cycle in IdM (Identity Management), including the following:

- Create user accounts
- Activate stage user accounts
- Preserve user accounts
- Delete active, stage, or preserved user accounts
- Restore preserved user accounts

1.1. USER LIFE CYCLE

Identity Management (IdM) supports three user account states:

- **Stage** users are not allowed to authenticate. This is an initial state. Some of the user account properties required for active users cannot be set, for example, group membership.
- Active users are allowed to authenticate. All required user account properties must be set in this state.
- **Preserved** users are former active users that are considered inactive and cannot authenticate to IdM. Preserved users retain most of the account properties they had as active users, but they are not part of any user groups.

You can delete user entries permanently from the IdM database.

IMPORTANT

Deleted user accounts cannot be restored. When you delete a user account, all the information associated with the account is permanently lost.

A new administrator can only be created by a user with administrator rights, such as the default admin user. If you accidentally delete all administrator accounts, the Directory Manager must create a new administrator manually in the Directory Server.

WARNING

Do not delete the **admin** user. As **admin** is a pre-defined user required by IdM, this operation causes problems with certain commands. If you want to define and use an alternative admin user, disable the pre-defined **admin** user with **ipa user-disable admin** after you granted admin permissions to at least one different user.

WARNING

Do not add local users to IdM. The Name Service Switch (NSS) always resolves IdM users and groups before resolving local users and groups. This means that, for example, IdM group membership does not work for local users.

1.2. ADDING USERS USING THE COMMAND LINE

You can add users as:

- Active user accounts which can be actively used by their users.
- **Stage** users cannot use these accounts. Create stage users if you want to prepare new user accounts. When users are ready to use their accounts, then you can activate them.

The following procedure describes adding active users to the IdM server with the **ipa user-add** command.

Similarly, you can create stage user accounts with the ipa stageuser-add command.

WARNING

IdM automatically assigns a unique user ID (UID) to new user accounts. You can assign a UID manually by using the **--uid=INT** option with the **ipa user-add** command, but the server does not validate whether the UID number is unique. Consequently, multiple user entries might have the same UID number. A similar problem can occur with user private group IDs (GIDs) if you assign a GID to a user account manually by using the **--gidnumber=INT** option. To check if you have multiple user entries with the same ID, enter **ipa user-find --uid=<uid> or ipa user-find --gidnumber=<gidnumber>.**

Red Hat recommends you do not have multiple entries with the same UIDs or GIDs. If you have objects with duplicate IDs, security identifiers (SIDs) are not generated correctly. SIDs are crucial for trusts between IdM and Active Directory and for Kerberos authentication to work correctly.

Prerequisites

- Administrator privileges for managing IdM or User Administrator role.
- Obtained a Kerberos ticket. For details, see link: Using kinit to log in to IdM manually .

Procedure

- 1. Open terminal and connect to the IdM server.
- 2. Add user login, user's first name, last name and optionally, you can also add their email address.

\$ ipa user-add user_login --first=first_name --last=last_name --email=email_address

IdM supports user names that can be described by the following regular expression:

[a-zA-Z0-9_.][a-zA-Z0-9_.-]{0,252}[a-zA-Z0-9_.\$-]?

NOTE

User names ending with the trailing dollar sign (\$) are supported to enable Samba 3.x machine support.

If you add a user name containing uppercase characters, IdM automatically converts the name to lowercase when saving it. Therefore, IdM always requires to enter user names in lowercase when logging in. Additionally, it is not possible to add user names which differ only in letter casing, such as **user** and **User**.

The default maximum length for user names is 32 characters. To change it, use the **ipa config-mod --maxusername** command. For example, to increase the maximum user name length to 64 characters:

\$ ipa config-mod --maxusername=64 Maximum username length: 64 ...

The **ipa user-add** command includes a lot of parameters. To list them all, use the ipa help command:

\$ ipa help user-add

For details about ipa help command, see What is the IPA help.

You can verify if the new user account is successfully created by listing all IdM user accounts:

\$ ipa user-find

This command lists all user accounts with details.

Additional resources

- Strengthening Kerberos security with PAC information
- Are user/group collisions supported in Red Hat Enterprise Linux? (Red Hat Knowledgebase)
- Users without SIDs cannot log in to IdM after an upgrade

1.3. ACTIVATING USERS USING THE COMMAND LINE

To activate a user account by moving it from stage to active, use the **ipa stageuser-activate** command.

Prerequisites

- Administrator privileges for managing IdM or User Administrator role.
- Obtained a Kerberos ticket. For details, see Using kinit to log in to IdM manually .

Procedure

- 1. Open terminal and connect to the IdM server.
- 2. Activate the user account with the following command:

```
$ ipa stageuser-activate user_login
-----
Stage user user_login activated
-------
```

You can verify if the new user account is successfully created by listing all IdM user accounts:

\$ ipa user-find

This command lists all user accounts with details.

1.4. PRESERVING USERS USING THE COMMAND LINE

You can preserve a user account if you want to remove it, but keep the option to restore it later. To preserve a user account, use the **--preserve** option with the **ipa user-del** or **ipa stageuser-del** commands.

Prerequisites

- Administrator privileges for managing IdM or User Administrator role.
- Obtained a Kerberos ticket. For details, see Using kinit to log in to IdM manually .

Procedure

- 1. Open terminal and connect to the IdM server.
- 2. Preserve the user account with the following command:

```
$ ipa user-del --preserve user_login
-----
Deleted user "user_login"
------
```

NOTE

Despite the output saying the user account was deleted, it has been preserved.

1.5. DELETING USERS USING THE COMMAND LINE

IdM (Identity Management) enables you to delete users permanently. You can delete:

- Active users with the following command: ipa user-del
- Stage users with the following command: ipa stageuser-del
- Preserved users with the following command: **ipa user-del**

When deleting multiple users, use the **--continue** option to force the command to continue regardless of errors. A summary of the successful and failed operations is printed to the **stdout** standard output stream when the command completes.

\$ *ipa user-del --continue user1 user2 user3*

If you do not use **--continue**, the command proceeds with deleting users until it encounters an error, after which it stops and exits.

Prerequisites

- Administrator privileges for managing IdM or User Administrator role.
- Obtained a Kerberos ticket. For details, see Using kinit to log in to IdM manually .

Procedure

- 1. Open terminal and connect to the IdM server.
- 2. Delete the user account with the following command:

```
$ ipa user-del user_login
-----
Deleted user "user_login"
-----
```

The user account has been permanently deleted from IdM.

1.6. RESTORING USERS USING THE COMMAND LINE

You can restore a preserved users to:

• Active users: ipa user-undel

• Stage users: ipa user-stage

Restoring a user account does not restore all of the account's previous attributes. For example, the user's password is not restored and must be set again.

Prerequisites

- Administrator privileges for managing IdM or User Administrator role.
- Obtained a Kerberos ticket. For details, see Using kinit to log in to IdM manually .

Procedure

- 1. Open terminal and connect to the IdM server.
- 2. Activate the user account with the following command:

```
$ ipa user-undel user_login
-----
Undeleted user account "user_login"
------
```

Alternatively, you can restore user accounts as staged:

```
$ ipa user-stage user_login
-----
Staged user account "user_login"
------
```

Verification

• You can verify if the new user account is successfully created by listing all IdM user accounts:

\$ ipa user-find

This command lists all user accounts with details.

1.7. ADDITIONAL RESOURCES

• Introduction to the IdM command-line utilities

CHAPTER 2. MANAGING USER ACCOUNTS USING THE IDM WEB UI

Identity Management (IdM) provides several stages that can help you to manage various user life cycle situations:

Creating a user account

Creating a stage user account before an employee starts their career in your company and be prepared in advance for the day when the employee appears in the office and want to activate the account.

You can omit this step and create the active user account directly. The procedure is similar to creating a stage user account.

Activating a user account

Activating the account the first working day of the employee.

Disabling a user account

If the user go to a parental leave for couple of months, you will need to disable the account temporarily.

Enabling a user account

When the user returns, you will need to re-enable the account.

Preserving a user account

If the user wants to leave the company, you will need to delete the account with a possibility to restore it because people can return to the company after some time.

Restoring a user account

Two years later, the user is back and you need to restore the preserved account.

Deleting a user account

If the employee is dismissed, delete the account without a backup.

2.1. USER LIFE CYCLE

Identity Management (IdM) supports three user account states: **Stage**, **Active**, **Preserved**. For details, see User life cycle section.

2.2. ADDING USERS IN THE WEB UI

Usually, you need to create a new user account before a new employee starts to work. Such a stage account is not accessible and you need to activate it later.

Prerequisites

• Administrator privileges for managing IdM or User Administrator role.

Procedure

- Log in to the IdM Web UI.
 For details, see Accessing the IdM Web UI in a web browser .
- 2. Go to **Users** → **Stage Users** tab.

Alternatively, you can add the user account in the **Users** → **Active users**, however, you cannot add user groups to the account.

- 3. Click the + Add icon.
- 4. Optional: In the **User login** field, add a login name.

 If you leave it empty, the IdM server creates the login name in the following pattern: The first letter of the first name and the surname. The whole login name can have up to 32 characters.
- 5. Fnter **First name** and **Last name** of the new user.
- 6. Optional: In the GID drop down menu, select groups in which the user should be included. Note that this option is only available on the **Active Users** dialog box.
- 7. Optional: In the **Password** and **Verify password** fields, enter your password and confirm it, ensuring they both match.
- 8. Click the Add button.

At this point, you can see the user account in the **Stage Users** or **Active Users** table.

If you click on the user name, you can edit advanced settings, such as adding a phone number, address, or occupation.

WARNING

IdM automatically assigns a unique user ID (UID) to new user accounts. You can assign a UID manually, or even modify an already existing UID. However, the server does not validate whether the new UID number is unique. Consequently, multiple user entries might have the same UID number assigned. A similar problem can occur with user private group IDs (GIDs) if you assign GIDs to user accounts manually. You can use the **ipa user-find --uid=<uid>** or **ipa user-find --gidnumber= <gidnumber>** commands on the IdM CLI to check if you have multiple user entries with the same ID.

You should not have multiple entries with the same UIDs or GIDs. If you have objects with duplicate IDs, security identifiers (SIDs) are not generated correctly. SIDs are crucial for trusts between IdM and Active Directory and for Kerberos authentication to work correctly.

Additional resources

- Strengthening Kerberos security with PAC information
- Are user/group collisions supported in Red Hat Enterprise Linux? (Red Hat Knowledgebase)
- Users without SIDs cannot log in to IdM after an upgrade

2.3. ACTIVATING STAGE USERS IN THE IDM WEB UI

You must follow this procedure to activate a stage user account, before the user can log in to IdM and before the user can be added to an IdM group.

Prerequisites

- Administrator privileges for managing the IdM Web UI or User Administrator role.
- At least one staged user account in IdM.

Procedure

- Log in to the IdM Web UI.
 For details, see Accessing the IdM Web UI in a web browser .
- 2. Go to **Users** → **Stage users** tab.
- 3. Click the checkbox of the user account you want to activate.
- 4. Click on the **Activate** button.
- 5. Click **OK** on the **Confirmation** dialog box.

If the activation is successful, the IdM Web UI displays a green confirmation that the user has been activated and the user account has been moved to **Active users**. The account is active and the user can authenticate to the IdM domain and IdM Web UI. The user is prompted to change their password on the first login.

Additionally, at this stage, you can add the active user account to user groups.

2.4. DISABLING USER ACCOUNTS IN THE WEB UI

You can disable active user accounts. Disabling a user account deactivates the account, therefore, user accounts cannot be used to authenticate and using IdM services, such as Kerberos, or perform any tasks.

Disabled user accounts still exist within IdM and all of the associated information remains unchanged. Unlike preserved user accounts, disabled user accounts remain in the active state and can be a member of user groups.

NOTE

After disabling a user account, any existing connections remain valid until the user's Kerberos TGT and other tickets expire. After the ticket expires, the user will not be able to renew it.

Prerequisites

• Administrator privileges for managing the IdM Web UI or User Administrator role.

Procedure

- Log in to the IdM Web UI.
 For details, see Accessing the IdM Web UI in a web browser .
- 2. Go to Users → Active users tab.

- 3. Click the checkbox of the user accounts you want to disable.
- 4. Click the **Disable** button.
- 5. Click the **OK** button on the **Confirmation** dialog box.

If the accounts are disabled successfully, you can verify this in the Status column in the **Active users** table.

2.5. ENABLING USER ACCOUNTS IN THE WEB UI

With IdM you can enable disabled active user accounts. Enabling a user account activates the disabled account.

Prerequisites

• Administrator privileges for managing the IdM Web UI or User Administrator role.

Procedure

- 1. Log in to the IdM Web UI.
- 2. Go to **Users** → **Active users** tab.
- 3. Click the checkbox of the user accounts you want to enable.
- 4. Click the Enable button.
- 5. Click the **OK** button on the **Confirmation** dialog box.

If the change is successful, you can verify this in the Status column in the Active Users table.

2.6. PRESERVING ACTIVE USERS IN THE IDM WEB UI

Preserving user accounts enables you to remove accounts from the **Active users** tab, yet keeping these accounts in IdM.

Preserve a user account if an employee leaves the company. If you want to disable user accounts for a couple of weeks or months (parental leave, for example), disable the account. For details, see Disabling user accounts in the Web UI. The preserved accounts are not active and users cannot use them to access your internal network, however, the account stays in the database with all the data.

You can move the restored accounts back to the active mode.

Prerequisites

• Administrator privileges for managing the IdM (Identity Management) Web UI or User Administrator role.

Procedure

- Log in to the IdM Web UI.
 For details, see Accessing the IdM Web UI in a web browser .
- 2. Go to **Users** → **Active users** tab.

- 3. Click the checkbox of the user accounts you want to preserve.
- 4. Click the **Delete** button.
- 5. On the **Remove users** dialog box, click **preserve**.
- 6. Click the **Delete** button.

The user account is moved to **Preserved users**.

If you need to restore preserved users, see the Restoring users in the IdM Web UI.

2.7. RESTORING USERS IN THE IDM WEB UI

IdM (Identity Management) enables you to restore preserved user accounts back to the active state. You can restore a preserved user to an active user or a stage user.

Prerequisites

Administrator privileges for managing the IdM Web UI or User Administrator role.

Procedure

- Log in to the IdM Web UI.
 For details, see Accessing the IdM Web UI in a web browser .
- 2. Go to Users → Preserved users tab.
- 3. Click the checkbox at the user accounts you want to restore.
- 4. Click the **Restore** button.
- 5. On the **Confirmation** dialog box, click the **OK** button.

The IdM Web UI displays a green confirmation and moves the user accounts to the **Active users** tab.

2.8. DELETING USERS IN THE IDM WEB UI

Deleting users is an irreversible operation, causing the user accounts to be permanently deleted from the IdM database, including group memberships and passwords. Any external configuration for the user, such as the system account and home directory, is not deleted, but is no longer accessible through IdM.

You can delete:

- Active users the IdM Web UI offers you with the options:
 - Preserving users temporarily. For details, see the Preserving active users in the IdM Web UI.
 - Deleting users permanently.
- Stage users you can just delete stage users permanently.
- Preserved users you can delete preserved users permanently.

The following procedure describes deleting active users. Similarly, you can delete user accounts on:

- The **Stage users** tab
- The **Preserved users** tab

Prerequisites

• Administrator privileges for managing the IdM Web UI or User Administrator role.

Procedure

- Log in to the IdM Web UI.
 For details, see Accessing the IdM Web UI in a web browser .
- Go to Users → Active users tab.
 Alternatively, you can delete the user account in the Users → Stage users or Users → Preserved users.
- 3. Click the **Delete** icon.
- 4. On the **Remove users** dialog box, click **delete**.
- 5. Click the **Delete** button.

The users accounts are permanently deleted from IdM.

CHAPTER 3. MANAGING USER ACCOUNTS USING ANSIBLE PLAYBOOKS

You can manage users in IdM using Ansible playbooks. After presenting the user life cycle, this chapter describes how to use Ansible playbooks for the following operations:

- Ensuring the presence of a single user listed directly in the **YML** file.
- Ensuring the presence of multiple users listed directly in the YML file.
- Ensuring the presence of multiple users listed in a **JSON** file that is referenced from the **YML** file.
- Ensuring the absence of users listed directly in the YML file.

3.1. USER LIFE CYCLE

Identity Management (IdM) supports three user account states: **Stage**, **Active**, **Preserved**. For details, see User life cycle section in the *Managing IdM users*, *groups*, *hosts*, *and access control rules* documentation.

3.2. ENSURING THE PRESENCE OF AN IDM USER USING AN ANSIBLE PLAYBOOK

The following procedure describes ensuring the presence of a user in IdM using an Ansible playbook.

Prerequisites

- On the control node:
 - You are using Ansible version 2.15 or later.
 - You have installed the **freeipa.ansible_freeipa** collection.
 - The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.
 - The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin_password** and that you have access to a file that stores the password protecting the **secret.yml** file.
- The target node, that is the node on which the **freeipa.ansible_freeipa** module is executed, is part of the IdM domain as an IdM client, server or replica.

Procedure

Create an Ansible playbook file with the data of the user whose presence in IdM you want to
ensure. To simplify this step, you can copy and modify the example in the
/usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/user/
add-user.yml file. For example, to create user named idm_user and add Password123 as the
user password:

- name: Playbook to handle users

hosts: ipaserver

vars_files:
- /home/user_name/MyPlaybooks/secret.yml

tasks:

name: Create user idm_user freeipa.ansible_freeipa.ipauser:

ipaadmin_password: "{{ ipaadmin_password }}"

name: idm_user first: Alice last: Acme uid: 1000111 gid: 10011

phone: "+555123457"

email: idm_user@acme.com

passwordexpiration: "2023-01-19 23:59:59"

password: "Password123" update_password: on_create

You must use the following options to add a user:

• name: the login name

- first: the first name string
- last: the last name string

For the full list of available user options, see the

/usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/README-user.md Markdown file.

NOTE

If you use the **update_password: on_create** option, Ansible only creates the user password when it creates the user. If the user is already created with a password, Ansible does not generate a new password.

2. Run the playbook:

\$ ansible-playbook --vault-password-file=password_file -v -i path_to_inventory_directory/inventory.file path_to_playbooks_directory/add-IdM-user.yml

Verification

- You can verify if the new user account exists in IdM by using the **ipa user-show** command:
 - 1. Log into **ipaserver** as admin:

\$ ssh admin@server.idm.example.com Password: [admin@server /]\$

2. Request a Kerberos ticket for admin:

\$ kinit admin

Password for admin@IDM.EXAMPLE.COM:

3. Request information about idm_user.

\$ ipa user-show idm_user

User login: idm_user First name: Alice Last name: Acme

....

The user named *idm_user* is present in IdM.

3.3. ENSURING THE PRESENCE OF MULTIPLE IDM USERS USING ANSIBLE PLAYBOOKS

The following procedure describes ensuring the presence of multiple users in IdM using an Ansible playbook.

Prerequisites

- On the control node:
 - You are using Ansible version 2.15 or later.
 - You have installed the **freeipa.ansible_freeipa** collection.
 - The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.
 - The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin_password** and that you have access to a file that stores the password protecting the **secret.yml** file.
- The target node, that is the node on which the freeipa.ansible_freeipa module is executed, is part of the IdM domain as an IdM client, server or replica.

Procedure

Create an Ansible playbook file with the data of the users whose presence you want to ensure in IdM. To simplify this step, you can copy and modify the example in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/user/ensure-users-present.yml file. For example, to create users idm_user_1, idm_user_2, and idm_user_3, and add Password123 as the password of idm_user_1:

- name: Playbook to handle users

hosts: ipaserver

vars_files:

- /home/user_name/MyPlaybooks/secret.yml

- name: Create user idm_users
freeipa.ansible_freeipa.ipauser:
 ipaadmin_password: "{{ ipaadmin_password }}"

users:

- name: idm_user_1

first: Alice last: Acme uid: 10001 gid: 10011

phone: "+555123457"

email: idm user@acme.com

passwordexpiration: "2023-01-19 23:59:59"

password: "Password123"

- name: idm_user_2

first: Bob last: Acme uid: 100011 gid: 10011

- name: idm_user_3

first: Eve last: Acme uid: 1000111 gid: 10011

NOTE

If you do not specify the **update_password**: **on_create** option, Ansible re-sets the user password every time the playbook is run: if the user has changed the password since the last time the playbook was run, Ansible re-sets password.

2. Run the playbook:

\$ ansible-playbook --vault-password-file=password_file -v -i path_to_inventory_directory/inventory.file path_to_playbooks_directory/addusers.yml

Verification

- You can verify if the user account exists in IdM by using the **ipa user-show** command:
 - 1. Log into **ipaserver** as administrator:

\$ ssh administrator@server.idm.example.com Password: [admin@server /]\$

2. Display information about idm_user_1:

\$ ipa user-show idm_user_1
User login: idm_user_1
First name: Alice
Last name: Acme
Password: True
....

The user named idm_user_1 is present in IdM.

3.4. ENSURING THE PRESENCE OF MULTIPLE IDM USERS FROM A JSON FILE USING ANSIBLE PLAYBOOKS

The following procedure describes how you can ensure the presence of multiple users in IdM using an Ansible playbook. The users are stored in a **JSON** file.

Prerequisites

- On the control node:
 - You are using Ansible version 2.15 or later.
 - You have installed the **freeipa.ansible freeipa** collection.
 - The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.
 - The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin_password** and that you have access to a file that stores the password protecting the **secret.yml** file.
- The target node, that is the node on which the **freeipa.ansible_freeipa** module is executed, is part of the IdM domain as an IdM client, server or replica.

Procedure

Create an Ansible playbook file with the necessary tasks. Reference the **JSON** file with the data
of the users whose presence you want to ensure. To simplify this step, you can copy and modify
the example in the

/usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/README-user.md file:

```
---
- name: Ensure users' presence
hosts: ipaserver

vars_files:
- /home/user_name/MyPlaybooks/secret.yml
tasks:
- name: Include users_present.json
include_vars:
    file: users_present.json

- name: Users present
freeipa.ansible_freeipa.ipauser:
    ipaadmin_password: "{{ ipaadmin_password }}"
users: "{{ users }}"
```

2. Create the **users.json** file, and add the IdM users into it. To simplify this step, you can copy and modify the example in the

/usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/README-user.md file. For example, to create users <code>idm_user_1</code>, <code>idm_user_2</code>, and <code>idm_user_3</code>, and add <code>Password123</code> as the password of <code>idm_user_1</code>:

```
{
"users": [
```

```
{
  "name": "idm_user_1",
  "first": "First 1",
  "last": "Last 1",
  "password": "Password123"
  },
  {
    "name": "idm_user_2",
    "first": "First 2",
    "last": "Last 2"
  },
  {
    "name": "idm_user_3",
    "first": "First 3",
    "last": "Last 3"
  }
  ]
}
```

3. Run the Ansible playbook. Specify the playbook file, the file storing the password protecting the **secret.yml** file, and the inventory file:

\$ ansible-playbook --vault-password-file=password_file -v -i path_to_inventory_directory/inventory.file path_to_playbooks_directory/ensure-userspresent-jsonfile.yml

Verification

- You can verify if the user accounts are present in IdM using the **ipa user-show** command:
 - 1. Log into **ipaserver** as administrator:

```
$ ssh administrator@server.idm.example.com
Password:
[admin@server /]$
```

2. Display information about idm_user_1:

```
$ ipa user-show idm_user_1
User login: idm_user_1
First name: Alice
Last name: Acme
Password: True
....
```

The user named idm_user_1 is present in IdM.

3.5. ENSURING THE ABSENCE OF USERS USING ANSIBLE PLAYBOOKS

The following procedure describes how you can use an Ansible playbook to ensure that specific users are absent from IdM.

Prerequisites

- On the control node:
 - You are using Ansible version 2.15 or later.
 - You have installed the **freeipa.ansible_freeipa** collection.
 - The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.
 - The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin_password** and that you have access to a file that stores the password protecting the **secret.yml** file.
- The target node, that is the node on which the freeipa.ansible_freeipa module is executed, is part of the IdM domain as an IdM client, server or replica.

Procedure

Create an Ansible playbook file with the users whose absence from IdM you want to ensure. To simplify this step, you can copy and modify the example in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/user/ensure-users-present.yml file. For example, to delete users idm_user_1, idm_user_2, and idm_user_3:

```
---
- name: Playbook to handle users
hosts: ipaserver

vars_files:
- /home/user_name/MyPlaybooks/secret.yml
tasks:
- name: Delete users idm_user_1, idm_user_2, idm_user_3
freeipa.ansible_freeipa.ipauser:
    ipaadmin_password: "{{ ipaadmin_password }}"
    users:
    - name: idm_user_1
    - name: idm_user_2
    - name: idm_user_3
    state: absent
```

2. Run the Ansible playbook. Specify the playbook file, the file storing the password protecting the **secret.yml** file, and the inventory file:

```
$ ansible-playbook --vault-password-file=password_file -v -i 
 path_to_inventory_directory/inventory.file path_to_playbooks_directory/delete-
users.yml
```

Verification

You can verify that the user accounts do not exist in IdM by using the **ipa user-show** command:

1. Log into **ipaserver** as administrator:

\$ ssh administrator@server.idm.example.com Password: [admin@server /]\$

2. Request information about idm_user_1:

\$ ipa user-show idm_user_1 ipa: ERROR: idm_user_1: user not found

The user named idm_user_1 does not exist in IdM.

Additional resources

- See the **README-user.md** Markdown file in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/ directory.
- See sample Ansible playbooks in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/user directory.

CHAPTER 4. MODIFYING USER AND GROUP ATTRIBUTES IN IDM

In Identity Management (IdM), information is stored as LDAP attributes. When you create a user entry in IdM, the entry is automatically assigned certain LDAP object classes. These object classes define what attributes are available to the user entry. For more information about the default user objects classes and how they are organized, see the table below.

Table 4.1. Default IdM user object classes

Object classes	Description
ipaobject, ipasshuser	IdM object classes
person, organizationalperson, inetorgperson, inetuser, posixAccount	Person object classes
krbprincipalaux, krbticketpolicyaux	Kerberos object classes
mepOriginEntry	Managed entries (template) object classes

As an administrator, you can modify the list of user object classes as well as the format of the attributes. For example, you can specify how many characters are allowed in a user name.

The way that user and group object classes and attributes are organized in IdM is called the IdM user and group schema.

4.1. THE DEFAULT IDM USER ATTRIBUTES

A user entry contains attributes. The values of certain attributes are set automatically, based on defaults, unless you set a specific value yourself. For other attributes, you have to set the values manually. Certain attributes, such as **First name**, require a value, whereas others, such as **Street address**, do not. As an administrator, you can configure the values generated or used by the default attributes. For more information, see the Default IdM user attributes table below.

Table 4.2. Default IdM user attributes

Web UI field	Command-line option	Required, optional, or default
User login	username	Required
First name	first	Required
Last name	last	Required
Full name	cn	Optional
Display name	displayname	Optional

Web UI field	Command-line option	Required, optional, or default
Initials	initials	Default
Home directory	homedir	Default
GECOS field	gecos	Default
Shell	shell	Default
Kerberos principal	principal	Default
Email address	email	Optional
Password	password	Optional. Note that the script prompts for a new password, rather than accepting a value with the argument.
User ID number	uid	Default
Group ID number	gidnumber	Default
Street address	street	Optional
City	city	Optional
State/Province	state	Optional
Zip code	postalcode	Optional
Telephone number	phone	Optional
Mobile telephone number	mobile	Optional
Pager number	pager	Optional
Fax number	fax	Optional
Organizational unit	orgunit	Optional
Job title	title	Optional
Manager	manager	Optional
Car license	carlicense	Optional

Web UI field	Command-line option	Required, optional, or default
	noprivate	Optional
SSH Keys	sshpubkey	Optional
Additional attributes	addattr	Optional
Department Number	departmentnumber	Optional
Employee Number	employeenumber	Optional
Employee Type	employeetype	Optional
Preferred Language	preferredlanguage	Optional

You can also add any attributes available in the Default IdM user object classes, even if no Web UI or command-line argument for that attribute exists.

4.2. CONSIDERATIONS IN CHANGING THE DEFAULT USER AND GROUP SCHEMA

User and group accounts are created with a predefined set of LDAP object classes applied to them. While the standard IdM-specific LDAP object classes and attributes cover most deployment scenarios, you can create custom object classes with custom attributes for user and group entries.

When you modify object classes, IdM provides the following validation:

- All of the object classes and their specified attributes must be known to the LDAP server.
- All default attributes that are configured for the entry must be supported by the configured object classes.

The IdM schema validation has limitations and the IdM server does not check that the defined user or group object classes contain all of the required object classes for IdM entries. For example, all IdM entries require the **ipaobject** object class. However, if the user or group schema is changed, the server does not check if this object class is included. If the object class is accidentally deleted and you then try to add a new user, the attempt fails.

All object class changes are atomic, not incremental. You must define the entire list of default object classes every time a change occurs. For example, you may decide to create a custom object class to store employee information such as birthdays and employment start dates. In this scenario, you cannot simply add the custom object class to the list. Instead, you must set the entire list of current default object classes **plus** the new object class. If you do not include the **existing** default object classes when you update the configuration, the current settings are overwritten. This causes serious performance problems.

NOTE

After you modify the list of default object classes, new user and group entries contain the custom object classes but any old entries are not modified.

4.3. MODIFYING USER OBJECT CLASSES IN THE IDM WEB UI

This procedure describes how you can use the IdM Web UI to modify object classes for future Identity Management (IdM) user entries. As a result, these entries will have different attributes than the current user entries do.

Prerequisites

• You are logged in as the IdM administrator.

Procedure

- 1. Open the IPA Server tab.
- 2. Select the **Configuration** subtab.
- 3. Scroll to the User Options area.

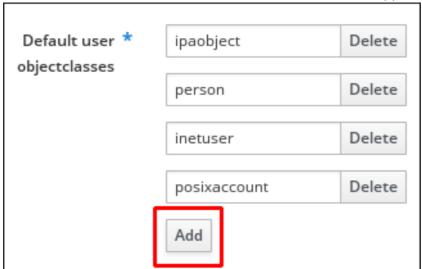

4. Keep all the object classes listed in the Default IdM user object classes table.

IMPORTANT

If any object classes required by IdM are not included, then subsequent attempts to add a user entry will fail with object class violations.

5. At the bottom of the users area, click **Add** for a new field to appear.

6. Enter the name of the user object class you want to add.

7. Click **Save** at the top of the **Configuration** page.

4.4. MODIFYING USER OBJECT CLASSES IN THE IDM CLI

This procedure describes how you can use the Identity Management (IdM) CLI to modify user object classes for future IdM user entries. As a result, these entries will have different attributes than the current user entries do.

Prerequisites

• You have enabled the **brace expansion** feature:

set -o braceexpand

• You are logged in as the IdM administrator.

Procedure

Use the ipa config-mod command to modify the current schema. For example, to add top and mailRecipient object classes to the future user entries:

[bjensen@server ~]\$ ipa config-mod --userobjectclasses= {person,organizationalperson,inetorgperson,inetuser,posixaccount,krbprincipalaux,krbticketpolicyaux,ipaobject,ipasshuser,mepOriginEntry,top,mailRecipient}

The command adds all the ten user object classes that are native to IdM as well as the two new ones, **top** and **mailRecipient**.

IMPORTANT

The information passed with the **config-mod** command overwrites the previous values. If any user object classes required by IdM are not included, then subsequent attempts to add a user entry will fail with object class violations.

Alternatively, you can add a user object class by using the **ipa config-mod --addattr ipauserobjectclasses=** *<user object class>* command. In this way, you do not risk forgetting a native IdM class in the list. For example, to add the **mailRecipient** user object class without overwriting the current configuration, enter **ipa config-mod --addattr ipauserobjectclasses=mailRecipient**. Analogously, to remove only the **mailRecipient** object class, enter **ipa config-mod --delattr ipauserobjectclasses=mailRecipient**.

4.5. MODIFYING GROUP OBJECT CLASSES IN THE IDM WEB UI

Identity Management (IdM) has the following default group object classes:

- top
- groupofnames
- nestedgroup
- ipausergroup

ipaobject

This procedure describes how you can use the IdM Web UI to add additional group object classes for future Identity Management (IdM) user group entries. As a result, these entries will have different attributes than the current the group entries do.

Prerequisites

• You are logged in as the IdM administrator.

Procedure

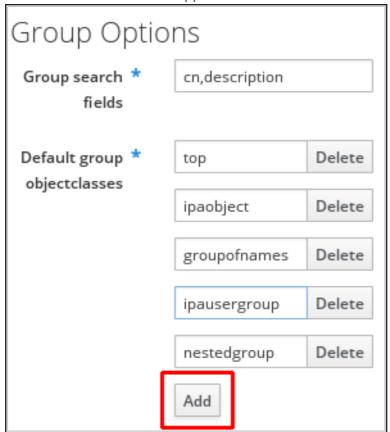

- 1. Open the IPA Server tab.
- 2. Select the **Configuration** subtab.
- 3. Locate the **Group Options** area.
- 4. Keep the default IdM group object classes.

IMPORTANT

If any group object classes required by IdM are not included, then subsequent attempts to add a group entry will fail with object class violations.

5. Click **Add** for a new field to appear.

- 6. Enter the name of the group object class you want to add.
- 7. Click **Save** at the top of the **Configuration** page.

4.6. MODIFYING GROUP OBJECT CLASSES IN THE IDM CLI

Identity Management (IdM) has the following default group object classes:

- top
- groupofnames
- nestedgroup
- ipausergroup
- ipaobject

This procedure describes how you can use the IdM Web UI to add additional group object classes for future Identity Management (IdM) user group entries. As a result, these entries will have different attributes than the current the group entries do.

Prerequisites

• You have enabled the **brace expansion** feature:

set -o braceexpand

• You are logged in as the IdM administrator.

Procedure

• Use the **ipa config-mod** command to modify the current schema. For example, to add **ipasshuser** and **employee** group object classes to the future user entries:

[bjensen@server ~]\$ ipa config-mod --groupobjectclasses= {top,groupofnames,nestedgroup,ipausergroup,ipaobject,ipasshuser,employeegroup}

The command adds all the default group object classes as well as the two new ones, **ipasshuser** and **employeegroup**.

IMPORTANT

If any group object classes required by IdM are not included, then subsequent attempts to add a group entry will fail with object class violations.

NOTE

Instead of the comma-separated list inside curly braces with no spaces allowed that is used in the example above, you can use the **--groupobjectclasses** argument repeatedly.

4.7. DEFAULT USER AND GROUP ATTRIBUTES IN IDM

Identity Management (IdM) uses a template when it creates new entries.

The template for users is more specific than the template for groups. IdM uses default values for several core attributes for IdM user accounts. These defaults can define actual values for user account

attributes, such as the home directory location, or they can define the formats of attribute values, such as the user name length. The template also defines the object classes assigned to users.

For groups, the template only defines the assigned object classes.

In the IdM LDAP directory, these default definitions are all contained in a single configuration entry for the IdM server, **cn=ipaconfig,cn=etc,dc=example,dc=com**.

You can modify the configuration of default user parameters in IdM by using the **ipa config-mod** command. The table below summarizes some of the key parameters, the command-line options that you can use with **ipa config-mod** to modify them, and the parameter descriptions.

Table 4.3. Default user parameters

Web UI field	Command-line option	Description
Maximum user name length	maxusername`	Sets the maximum number of characters for user names. Default: 32.
Root for home directories	homedirectory	Sets the default directory for user home directories. Default: /home.
Default shell	defaultshell	Sets the default shell for users. Default: /bin/sh.
Default user group	defaultgroup	Sets the default group for newly created accounts. Default: ipausers .
Default e-mail domain	emaildomain	Sets the email domain for creating addresses based on user accounts. Default: server domain.
Search time limit	searchtimelimit	Sets the maximum time in seconds for a search before returning results.
Search size limit	searchrecordslimit	Sets the maximum number of records to return in a search.
User search fields	usersearch	Defines searchable fields in user entries, impacting server performance if too many attributes are set.
Group search fields	groupsearch	Defines searchable fields in group entries.
Certificate subject base		Sets the base DN for creating subject DNs for client certificates during setup.
Default user object classes	userobjectclasses	Defines object classes for creating user accounts. Must provide a complete list as it overwrites the existing one.
Default group object classes	 groupobjectclasses	Defines object classes for creating group accounts. Must provide a complete list.

Web UI field	Command-line option	Description
Password expiration notification	pwdexpnotify	Defines the number of days before a password expires for sending a notification.
Password plug-in features		Sets the format of allowable passwords for users.

4.8. VIEWING AND MODIFYING USER AND GROUP CONFIGURATION IN THE IDM WEB UI

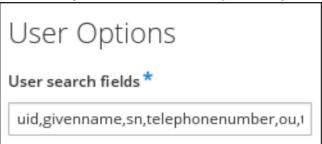

You can view and modify the configuration of the default user and group attributes in the Identity Management (IdM) Web UI.

Prerequisites

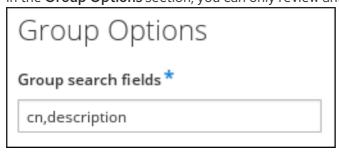

• You are logged in as IdM admin.

Procedure

- 1. Open the IPA Server tab.
- 2. Select the **Configuration** subtab.
- 3. The User Options section has multiple fields you can review and edit.

- 4. For example, to change the default shell for future IdM users from /bin/sh to /bin/bash, locate the Default shell field, and replace /bin/sh with /bin/bash.
- 5. In the Group Options section, you can only review and edit the Group search fields field.

Click the Save button at the top of the screen.
 The newly saved configuration will be applied to future IdM user and group accounts. The current accounts remain unchanged.

4.9. VIEWING AND MODIFYING USER AND GROUP CONFIGURATION IN THE IDM CLI

You can view and modify the configuration of the current or default user and group attributes in the Identity Management (IdM) CLI.

Prerequisites

You have the IdM admin credentials.

Procedure

• The **ipa config-show** command displays the most common attribute settings. Use the **--all** option for a complete list:

[bjensen@server ~]\$ ipa config-show --all

dn: cn=ipaConfig,cn=etc,dc=example,dc=com

Maximum username length: 32 Home directory base: /home

Default shell: /bin/sh

Default users group: ipausers

Default e-mail domain: example.com

Search time limit: 2 Search size limit: 100

User search fields: uid, givenname, sn, telephonenumber, ou, title

Group search fields: cn,description Enable migration mode: FALSE

Certificate Subject base: O=EXAMPLE.COM

Default group objectclasses: top, groupofnames, nestedgroup, ipausergroup, ipaobject Default user objectclasses: top, person, organizationalperson, inetorgperson, inetuser,

posixaccount, krbprincipalaux, krbticketpolicyaux, ipaobject, ipasshuser

Password Expiration Notification (days): 4
Password plugin features: AllowNThash

SELinux user map order: guest u:s0\$xguest u:s0\$user u:s0\$staff u:s0-

s0:c0.c1023\$unconfined u:s0-s0:c0.c1023

Default SELinux user: unconfined_u:s0-s0:c0.c1023

Default PAC types: MS-PAC, nfs:NONE

cn: ipaConfig

objectclass: nsContainer, top, ipaGuiConfig, ipaConfigObject

• Use the **ipa config-mod** command to modify an attribute. For example, to change the default shell for future IdM users from **/bin/sh** to **/bin/bash**, enter:

[bjensen@server ~]\$ ipa config-mod --defaultshell "/bin/bash"

For more **ipa config-mod** options, see the Default user parameters table.

The new configuration will be applied to future IdM user and group accounts. The current accounts remain unchanged.

4.10. ADDITIONAL RESOURCES

• Managing Directory Server attributes and values in DS 13

CHAPTER 5. MANAGING USER PASSWORDS IN IDM

5.1. WHO CAN CHANGE IDM USER PASSWORDS AND HOW

Regular users without the permission to change other users' passwords can change only their own personal password. The new password must meet the IdM password policies applicable to the groups of which the user is a member. For details on configuring password policies, see Defining IdM password policies.

Administrators and users with password change rights can set initial passwords for new users and reset passwords for existing users. These passwords:

- Do not have to meet the IdM password policies.
- Expire after the first successful login. When this happens, IdM prompts the user to change the expired password immediately. To disable this behavior, see Enabling password reset in IdM without prompting the user for a password change at the next login.

Note that the LDAP Directory Manager (DM) user can change user passwords using LDAP tools. A new password can override any IdM password policies. Passwords set by DM do not expire after the first login.

5.2. CHANGING YOUR USER PASSWORD IN THE IDM WEB UI

As an Identity Management (IdM) user, you can change your user password in the IdM Web UI.

Prerequisites

• You are logged in to the IdM Web UI.

Procedure

- 1. In the upper right corner, click the name of the user who is logged into the IdM Web UI.
- 2. Select Change password.
- 3. Enter the current password.
- 4. Enter the new password in the **New Password** field.
- 5. Confirm the new password by entering it in the **Verify Password** field.
- 6. Click Reset Password.

5.3. RESETTING ANOTHER USER'S PASSWORD IN THE IDM WEB UI

As an administrative user of Identity Management (IdM), you can change passwords for other users in the IdM Web UI.

Prerequisites

• You are logged in to the IdM Web UI as an administrative user.

Procedure

- 1. Select Identity>Users.
- 2. Click the name of the user to edit.
- 3. Click **Actions** and select **Reset password**.
- 4. Enter the new password in the New Password field.
- 5. Confirm the new password by entering it in the **Verify Password** field.
- 6. Click Reset Password.

5.4. RESETTING THE DIRECTORY MANAGER USER PASSWORD

If you lose the Identity Management (IdM) Directory Manager password, you can reset it.

Prerequisites

• You have **root** access to an IdM server.

Procedure

1. Generate a new password hash by using the **pwdhash** command. For example:

pwdhash -D /etc/dirsrv/slapd-IDM-EXAMPLE-COM password {PBKDF2_SHA256}AAAgABU0bKhyjY53NcxY33ueoPjOUWtl4iyYN5uW...

By specifying the path to the Directory Server configuration, you automatically use the password storage scheme set in the **nsslapd-rootpwstoragescheme** attribute to encrypt the new password.

- 2. On every IdM server in your topology, execute the following steps:
 - a. Stop all IdM services installed on the server:
 - # ipactl stop
 - b. Edit the /etc/dirsrv/IDM-EXAMPLE-COM/dse.ldif file and set the nsslapd-rootpw attribute to the value generated by the pwdhash command:

nsslapd-rootpw: {PBKDF2_SHA256}AAAgABU0bKhyjY53NcxY33ueoPjOUWtl4iyYN5uW...

c. Start all IdM services installed on the server:

ipactl start

5.5. CHANGING YOUR USER PASSWORD OR RESETTING ANOTHER USER'S PASSWORD IN IDM CLI

You can change your user password using the Identity Management (IdM) command-line interface (CLI). If you are an administrative user, you can use the CLI to reset another user's password.

Prerequisites

- You have obtained a ticket-granting ticket (TGT) for an IdM user.
- If you are resetting another user's password, you must have obtained a TGT for an administrative user in IdM.

Procedure

• Enter the **ipa user-mod** command with the name of the user and the **--password** option. The command will prompt you for the new password.

```
$ ipa user-mod idm_user --password
Password:
Enter Password again to verify:
-----
Modified user "idm_user"
-------
```

Note that you can also use the **ipa passwd** idm_user command instead of **ipa user-mod**.

5.6. ENABLING PASSWORD RESET IN IDM WITHOUT PROMPTING THE USER FOR A PASSWORD CHANGE AT THE NEXT LOGIN

By default, when an administrator resets another user's password, the password expires after the first successful login.

As IdM Directory Manager, you can specify the following privileges for individual IdM administrators:

- They can perform password change operations without requiring users to change their passwords subsequently on their first login.
- They can bypass the password policy so that no strength or history enforcement is applied.

WARNING

Bypassing the password policy can be a security threat. Exercise caution when selecting users to whom you grant these additional privileges.

Prerequisites

• You know the Directory Manager password.

Procedure

On every Identity Management (IdM) server in the domain, make the following changes:

1. Enter the **Idapmodify** command to modify LDAP entries. Specify the name of the IdM server and the 389 port and press Enter:

\$ Idapmodify -x -D "cn=Directory Manager" -W -h server.idm.example.com -p 389 Enter LDAP Password:

- 2. Enter the Directory Manager password.
- 3. Enter the distinguished name for the **ipa_pwd_extop** password synchronization entry and press Enter:

dn: cn=ipa_pwd_extop,cn=plugins,cn=config

4. Specify the **modify** type of change and press Enter:

changetype: modify

5. Specify what type of modification you want LDAP to execute and to which attribute. Press Fnter:

add: passSyncManagersDNs

6. Specify the administrative user accounts in the **passSyncManagersDNs** attribute. The attribute is multi-valued. For example, to grant the **admin** user the password resetting powers of Directory Manager:

passSyncManagersDNs: \ uid=admin,cn=users,cn=accounts,dc=example,dc=com

7. Press Enter twice to stop editing the entry.

The admin user, listed under passSyncManagerDNs, now has the additional privileges.

5.7. CHECKING IF AN IDM USER'S ACCOUNT IS LOCKED

As an Identity Management (IdM) administrator, you can check if an IdM user's account is locked. For that, you must compare a user's maximum allowed number of failed login attempts with the number of the user's actual failed logins.

Prerequisites

You have obtained the ticket-granting ticket (TGT) of an administrative user in IdM.

Procedure

1. Display the status of the user account to see the number of failed logins:

\$ ipa user-status example_user
-----Account disabled: False
-----Server: idm.example.com
Failed logins: 8

Last successful authentication: N/A

Last failed authentication: 20220229080317Z

Time now: 2022-02-29T08:04:46Z

Number of entries returned 1

2. Display the number of allowed login attempts for a particular user:

\$ ipa pwpolicy-show --user example_user

Group: global_policy Max lifetime (days): 90 Min lifetime (hours): 1

History size: 0

Character classes: 0

Min length: 8 Max failures: 6

Failure reset interval: 60 Lockout duration: 600 Grace login limit: -1

3. Compare the number of failed logins as displayed in the output of the **ipa user-status** command with the **Max failures** number displayed in the output of the **ipa pwpolicy-show** command. If the number of failed logins equals that of maximum allowed login attempts, the user account is locked.

Additional resources

• Unlocking user accounts after password failures in IdM

5.8. UNLOCKING USER ACCOUNTS AFTER PASSWORD FAILURES IN IDM

If a user attempts to log in using an incorrect password a certain number of times, Identity Management (IdM) locks the user account, which prevents the user from logging in. For security reasons, IdM does not display any warning message that the user account has been locked. Instead, the CLI prompt might continue asking the user for a password again and again.

IdM automatically unlocks the user account after a specified amount of time has passed. Alternatively, you can unlock the user account manually with the following procedure.

Prerequisites

• You have obtained the ticket-granting ticket of an IdM administrative user.

Procedure

• To unlock a user account, use the **ipa user-unlock** command.

\$ ipa user-unlock idm_user
----Unlocked account "idm_user"

After this, the user can log in again.

Additional resources

• Checking if an IdM user's account is locked

5.9. ENABLING THE TRACKING OF LAST SUCCESSFUL KERBEROS AUTHENTICATION FOR USERS IN IDM

For performance reasons, Identity Management (IdM) running in Red Hat Enterprise Linux 8 does not store the time stamp of the last successful Kerberos authentication of a user. As a consequence, certain commands, such as **ipa user-status**, do not display the time stamp.

Prerequisites

- You have obtained the ticket-granting ticket (TGT) of an administrative user in IdM.
- You have **root** access to the IdM server on which you are executing the procedure.

Procedure

1. Display the currently enabled password plug-in features:

ipa config-show | grep "Password plugin features"

Password plugin features: pass:quotes[AllowNThash], pass:quotes[KDC:Disable Last Success]

The output shows that the **KDC:Disable Last Success** plug-in is enabled. The plug-in hides the last successful Kerberos authentication attempt from being visible in the ipa user-status output.

2. Add the **--ipaconfigstring**=**feature** parameter for every feature to the **ipa config-mod** command that is currently enabled, except for **KDC:Disable Last Success**:

ipa config-mod --ipaconfigstring='AllowNThash'

This command enables only the **AllowNThash** plug-in. To enable multiple features, specify the **--ipaconfigstring**=*feature* parameter separately for each feature.

3. Restart IdM:

ipactl restart

CHAPTER 6. DEFINING IDM PASSWORD POLICIES

This chapter describes Identity Management (IdM) password policies and how to add a new password policy in IdM.

For details, how to

6.1. WHAT IS A PASSWORD POLICY

A password policy is a set of rules that passwords must meet. For example, a password policy can define the minimum password length and the maximum password lifetime. All users affected by this policy are required to set a sufficiently long password and change it frequently enough to meet the specified conditions. In this way, password policies help reduce the risk of someone discovering and misusing a user's password.

6.2. PASSWORD POLICIES IN IDM

Passwords are the most common way for Identity Management (IdM) users to authenticate to the IdM Kerberos domain. Password policies define the requirements that these IdM user passwords must meet.

NOTE

The IdM password policy is set in the underlying LDAP directory, but the Kerberos Key Distribution Center (KDC) enforces the password policy.

Password policy attributes lists the attributes you can use to define a password policy in IdM.

Table 6.1. Password Policy Attributes

Attribute	Explanation	Example
Max lifetime	The maximum amount of time in days that a password is valid before a user must reset it. The default value is 90 days. Note that if the attribute is set to 0, the password never expires.	Max lifetime = 180 User passwords are valid only for 180 days. After that, IdM prompts users to change them.
Min lifetime	The minimum amount of time in hours that must pass between two password change operations.	Min lifetime = 1 After users change their passwords, they must wait at least 1 hour before changing them again.
History size	The number of previous passwords that are stored. A user cannot reuse a password from their password history but can reuse old passwords that are not stored.	History size = 0 In this case, the password history is empty and users can reuse any of their previous passwords.

Attribute	Explanation	Example
Character classes	The number of different character classes the user must use in the password. The character classes are: * Uppercase characters * Lowercase characters * Digits * Special characters, such as comma (,), period (.), asterisk (*) * Other UTF-8 characters Using a character three or more times in a row decreases the character class by one. For example: * Secret1 has 3 character classes: uppercase, lowercase, digits * Secret111 has 2 character classes: uppercase, lowercase, digits, and a -1 penalty for using 1 repeatedly	Character classes = 0 The default number of classes required is 0. To configure the number, run the ipa pwpolicy-mod command with the-minclasses option. See also the Important note below this table.
Min length	The minimum number of characters in a password. If any of the additional password policy options are set, then the minimum length of passwords is 6 characters.	Min length = 8 Users cannot use passwords shorter than 8 characters.
Max failures	The maximum number of failed login attempts before IdM locks the user account.	Max failures = 6 IdM locks the user account when the user enters a wrong password 7 times in a row.
Failure reset interval	The amount of time in seconds after which IdM resets the current number of failed login attempts.	Failure reset interval = 60 If the user waits for more than 1 minute after the number of failed login attempts defined in Max failures , the user can attempt to log in again without risking a user account lock.
Lockout duration	The amount of time in seconds that the user account is locked after the number of failed login attempts defined in Max failures .	Lockout duration = 600 Users with locked accounts are unable to log in for 10 minutes.

IMPORTANT

Use the English alphabet and common symbols for the character classes requirement if you have a diverse set of hardware that may not have access to international characters and symbols. For more information about character class policies in passwords, see the Red Hat Knowledgebase solution What characters are valid in a password? .

6.3. PASSWORD POLICY PRIORITIES IN IDM

Password policies help reduce the risk of someone discovering and misusing a user's password. The default password policy is the *global password policy*. You can also create additional group password policies. The global policy rules apply to all users without a group password policy. Group password policies apply to all members of the corresponding user group.

Note that only one password policy can be in effect at a time for any user. If a user has multiple password policies assigned, one of them takes precedence based on priority according to the following rules:

- Every group password policy has a priority set. The lower the value, the higher the policy's priority. The lowest supported value is **0**.
- If multiple password policies are applicable to a user, the policy with the lowest priority value takes precedence. All rules defined in other policies are ignored.
- The password policy with the lowest priority value applies to all password policy attributes, even the attributes that are not defined in the policy.

The global password policy does not have a priority value set. It serves as a fallback policy when no group policy is set for a user. The global policy can never take precedence over a group policy.

NOTE

The **ipa pwpolicy-show --user=user_name** command shows which policy is currently in effect for a particular user.

6.4. ADDING A NEW PASSWORD POLICY IN IDM USING THE WEBUI OR THE CLI

Password policies help reduce the risk of someone discovering and misusing a user's password. The default password policy is the *global password policy*. You can also create additional group password policies.

6.4.1. Adding a new password policy in the IdM WebUI

Password policies help reduce the risk of someone discovering and misusing a user's password. The default password policy is the *global password policy*. You can also create additional group password policies.

Prerequisites

- A user group to which the policy applies.
- A priority assigned to the policy

- .

Procedure

- 1. Log in to the IdM Web UI. For details, see Accessing the IdM Web UI in a web browser .
- 2. Select Policy>Password Policies.
- 3. Click Add.
- 4. Define the user group and priority.
- 5. Click Add to confirm.

To configure the attributes of the new password policy, see Password policies in IdM.

Additional resources

• See Password policy priorities in IdM .

6.4.2. Adding a new password policy in the IdM CLI

Password policies help reduce the risk of someone discovering and misusing a user's password. The default password policy is the *global password policy*. You can also create additional group password policies.

Prerequisites

- A user group to which the policy applies.
- A priority assigned to the policy

Procedure

- 1. Open terminal and connect to the IdM server.
- 2. Use the **ipa pwpolicy-add** command. Specify the user group and priority:

\$ ipa pwpolicy-add Group: group_name Priority: priority_level

3. Optional. Use the **ipa pwpolicy-find** command to verify that the policy has been successfully added:

\$ ipa pwpolicy-find

To configure the attributes of the new password policy, see Password policies in IdM.

Additional resources

• See Password policy priorities in IdM .

6.5. ADDITIONAL PASSWORD POLICY OPTIONS IN IDM

As an Identity Management (IdM) administrator, you can strengthen the default password requirements by enabling additional password policy options based on the **libpwquality** feature set. The additional password policy options include the following:

--maxrepeat

Specifies the maximum acceptable number of same consecutive characters in the new password.

--maxsequence

Specifies the maximum length of monotonic character sequences in the new password. Examples of such a sequence are **12345** or **fedcb**. Most such passwords will not pass the simplicity check.

--dictcheck

If nonzero, checks whether the password, with possible modifications, matches a word in a dictionary. Currently **libpwquality** performs the dictionary check using the **cracklib** library.

--usercheck

If nonzero, checks whether the password, with possible modifications, contains the user name in some form. It is not performed for user names shorter than 3 characters.

You cannot apply the additional password policy options to existing passwords. If you apply any of the additional options, IdM automatically sets the **--minlength** option, the minimum number of characters in a password, to **6** characters.

NOTE

In a mixed environment with RHEL 7, RHEL 8, RHEL 9, and RHEL 10 servers, you can enforce the additional password policy settings only on servers running on RHEL 8.4 and later. If a user is logged in to an IdM client and the IdM client is communicating with an IdM server running on RHEL 8.3 or earlier, then the new password policy requirements set by the system administrator will not be applied. To ensure consistent behavior, upgrade or update all servers to RHEL 8.4 and later.

Additional resources:

- Applying additional password policies to an IdM group
- pwquality(3) man page on your system

6.6. APPLYING ADDITIONAL PASSWORD POLICY OPTIONS TO AN IDM GROUP

Follow this procedure to apply additional password policy options in Identity Management (IdM). The example describes how to strengthen the password policy for the **managers** group by making sure that the new passwords do not contain the users' respective user names and that the passwords contain no more than two identical characters in succession.

Prerequisites

- You are logged in as an IdM administrator.
- The managers group exists in IdM.
- The managers password policy exists in IdM.

Procedure

1. Apply the user name check to all new passwords suggested by the users in the **managers** group:

\$ ipa pwpolicy-mod --usercheck=True managers

NOTE

If you do not specify the name of the password policy, the default **global_policy** is modified.

2. Set the maximum number of identical consecutive characters to 2 in the **managers** password policy:

\$ ipa pwpolicy-mod --maxrepeat=2 managers

A password now will not be accepted if it contains more than 2 identical consecutive characters. For example, the **eR873mUi111YJQ** combination is unacceptable because it contains three 1s in succession.

Verification

1. Add a test user named test_user:

\$ ipa user-add test_user
First name: test
Last name: user
-----Added user "test_user"

- 2. Add the test user to the **managers** group:
 - a. In the IdM Web UI, click **Identity** \rightarrow **Groups** \rightarrow **User Groups**.
 - b. Click managers.
 - c. Click Add.
 - d. In the Add users into user group 'managers' page, check test_user.
 - e. Click the > arrow to move the user to the **Prospective** column.
 - f. Click Add.
- 3. Reset the password for the test user:
 - a. Go to **Identity** → **Users**.
 - b. Click test_user.
 - c. In the Actions menu, click Reset Password.
 - d. Enter a temporary password for the user.
- 4. On the command line, try to obtain a Kerberos ticket-granting ticket (TGT) for the test_user:

\$ kinit test_user

- a. Enter the temporary password.
- b. The system informs you that you must change your password. Enter a password that contains the user name of **test_user**:

Password expired. You must change it now.

Enter new password:

Enter it again:

Password change rejected: Password not changed.

Unspecified password quality failure while trying to change password.

Please try again.

NOTE

Kerberos does not have fine-grained error password policy reporting and, in certain cases, does not provide a clear reason why a password was rejected.

c. The system informs you that the entered password was rejected. Enter a password that contains three or more identical characters in succession:

Password change rejected: Password not changed.

Unspecified password quality failure while trying to change password.

Please try again.

Enter new password:

Enter it again:

d. The system informs you that the entered password was rejected. Enter a password that meets the criteria of the **managers** password policy:

Password change rejected: Password not changed.

Unspecified password quality failure while trying to change password.

Please try again.

Enter new password:

Enter it again:

5. View the obtained TGT:

\$ klist

Ticket cache: KCM:0:33945

Default principal: test_user@IDM.EXAMPLE.COM

Valid starting Expires Service principal

07/07/2021 12:44:44 07/08/2021 12:44:44

krbtgt@IDM.EXAMPLE.COM@IDM.EXAMPLE.COM

The managers password policy now works correctly for users in the managers group.

Additional resources

- Additional password policies in IdM
- Using an Ansible playbook to apply additional password policy options to an IdM group

Additional resources

• Defining IdM password policies using an Ansible playbook

CHAPTER 7. MANAGING EXPIRING PASSWORD NOTIFICATIONS

You can use the Expiring Password Notification (EPN) tool, provided by the **ipa-client-epn** package, to build a list of Identity Management (IdM) users whose passwords are expiring in a configured amount of time. To install, configure, and use the EPN tool, refer to the relevant sections.

7.1. WHAT IS THE EXPIRING PASSWORD NOTIFICATION TOOL

The Expiring Password Notification (EPN) tool is a standalone tool you can use to build a list of Identity Management (IdM) users whose passwords are expiring in a configured amount of time.

IdM administrators can use FPN to:

- Display a list of affected users in JSON format, which is created when run in dry-run mode.
- Calculate how many emails will be sent for a given day or date range.
- Send password expiration email notifications to users.
- Configure the **ipa-epn.timer** to run the EPN tool daily and send an email to users whose passwords are expiring within the defined future date ranges.
- Customize the email notification to send to users.

NOTE

If a user account is disabled, no email notifications are sent if the password is going to expire.

7.2. INSTALLING THE EXPIRING PASSWORD NOTIFICATION TOOL

Follow this procedure to install the Expiring Password Notification (EPN) tool.

Prerequisites

• Install the EPN tool on either an Identity Management (IdM) replica or an IdM client with a local Postfix SMTP server configured as a smart host.

Procedure

Install the EPN tool:

dnf install ipa-client-epn

7.3. RUNNING THE EPN TOOL TO SEND EMAILS TO USERS WHOSE PASSWORDS ARE EXPIRING

You can use the Expiring Password Notification (EPN) tool to send emails to Identity Management (IdM) users whose passwords are expiring. You can choose one of the following methods:

• Update the **epn.conf** configuration file and enable the ipa-epn.timer tool.

Update the epn.conf configuration file and run the EPN tool directly on the command line.

NOTE

The EPN tool is stateless. If the EPN tool fails to email any of the users whose passwords are expiring on a given day, the EPN tool does not save a list of those users.

Prerequisites

- The **ipa-client-epn** package is installed. See Installing the Expiring Password Notification tool.
- Customize the **ipa-epn** email template if required. See Modifying the Expiring Password Notification email template.

Procedure

1. Open the **epn.conf** configuration file.

vi /etc/ipa/epn.conf

2. Update the **notify_ttls** option as required. The default is to notify users whose passwords are expiring in 28, 14, 7, 3, and 1 day(s).

notify_ttls = 28, 14, 7, 3, 1

NOTE

You must also activate the **ipa-epn.timer** tool to ensure that emails are sent.

3. Configure your SMTP server and port:

smtp_server = localhost smtp_port = 25

4. Specify the email address from which the email expiration notification is sent. Any unsuccessfully delivered emails are returned to this address.

mail_from = admin-email@example.com

- 5. Optional: If you want to use an encrypted channel of communication, specify the credentials to be used:
 - Specify the path to a single file in PEM format containing the certificate to be used by EPN to authenticate with the SMTP server:

smtp_client_cert = /etc/pki/tls/certs/client.pem

NOTE

EPN is an SMTP client. The purpose of the certificate is client authentication, not secure SMTP delivery.

• You can specify the path to a file that contains the private key. If not specified, the private key is taken from the certificate file.

```
smtp_client_key = /etc/pki/tls/certs/client.key
```

• If the private key is encrypted, specify the password for decrypting it.

```
smtp_client_key_pass = Secret123!
```

- 6. Save the /etc/ipa/epn.conf file.
- 7. Run the EPN tool in dry-run mode to generate a list of the users to whom the password expiration email notification would be sent if you run the tool without the **--dry-run** option.

NOTE

If the list of users returned is very large and you run the tool without the **--dry-run** option, this might cause an issue with your email server.

8. Run the EPN tool without the **--dry-run** option to send expiration emails to the list of all the users returned when you ran the EPN tool in dry-run mode:

```
"krbpasswordexpiration": "2020-12-17 15:51:53",
    "mail": "['user5@ipa.test']"
    }
]
The IPA-EPN command was successful
```

9. You can add EPN to any monitoring system and invoke it with the **--from-nbdays** and **--to-nbdays** options to determine how many users passwords are going to expire within a specific time frame:

ipa-epn --from-nbdays 8 --to-nbdays 12

NOTE

If you invoke the EPN tool with the **--from-nbdays** and **--to-nbdays** options, it is automatically executed in dry-run mode.

Verification

• Run the EPN tool and verify an email notification is sent.

Additional resources

- The **ipa-epn** man page on your system.
- The epn.conf man page on your system.

7.4. ENABLING THE IPA-EPN.TIMER TO SEND AN EMAIL TO ALL USERS WHOSE PASSWORDS ARE EXPIRING

Follow this procedure to use **ipa-epn.timer** to run the Expiring Password Notification (EPN) tool to send emails to users whose passwords are expiring. The **ipa-epn.timer** parses the **epn.conf** file and sends an email to users whose passwords are expiring within the defined future date ranges configured in that file.

Prerequisites

- The **ipa-client-epn** package is installed. See Installing the Expiring Password Notification tool
- Customize the **ipa-epn** email template if required. See Modifying the Expiring Password Notification email template

Procedure

Start the ipa-epn.timer:

systemctl start ipa-epn.timer

Once you start the timer, by default, the EPN tool is run every day at 1 a.m.

Additional resources

• The **ipa-epn** man page on your system.

7.5. MODIFYING THE EXPIRING PASSWORD NOTIFICATION EMAIL TEMPLATE

Follow this procedure to customize the Expiring Password Notification (EPN) email message template.

Prerequisites

• The **ipa-client-epn** package is installed.

Procedure

1. Open the EPN message template:

vi /etc/ipa/epn/expire_msg.template

2. Update the template text as required.

```
Hi {{ fullname }},
```

Your password will expire on {{ expiration }}.

Please change it as soon as possible.

You can use the following variables in the template.

• User ID: uid

• Full name: fullname

• First name: first

Last name: last

• Password expiration date: expiration

3. Save the message template file.

Verification

• Run the EPN tool and verify the email notification contains the updated text.

Additional resources

• See the **ipa-epn** man page on your system.

CHAPTER 8. GRANTING SUDO ACCESS TO AN IDM USER ON AN IDM CLIENT

Learn more about granting **sudo** access to users in Identity Management.

8.1. SUDO ACCESS ON AN IDM CLIENT

System administrators can grant **sudo** access to allow non-root users to execute administrative commands that are normally reserved for the **root** user. Consequently, when users need to perform an administrative command normally reserved for the **root** user, they precede that command with **sudo**. After entering their password, the command is executed as if they were the **root** user. To execute a **sudo** command as another user or group, such as a database service account, you can configure a *RunAs alias* for a **sudo** rule.

If a Red Hat Enterprise Linux (RHEL) 8 host is enrolled as an Identity Management (IdM) client, you can specify **sudo** rules defining which IdM users can perform which commands on the host in the following ways:

- Locally in the /etc/sudoers file
- Centrally in IdM

You can create a central sudo rule for an IdM client using the command line (CLI) and the IdM Web UI.

You can also configure password-less authentication for **sudo** using the Generic Security Service Application Programming Interface (GSSAPI), the native way for UNIX-based operating systems to access and authenticate Kerberos services. You can use the **pam_sss_gss.so** Pluggable Authentication Module (PAM) to invoke GSSAPI authentication via the SSSD service, allowing users to authenticate to the **sudo** command with a valid Kerberos ticket.

Additional resources

Managing sudo access

8.2. GRANTING SUDO ACCESS TO AN IDM USER ON AN IDM CLIENT USING THE CLI

In Identity Management (IdM), you can grant **sudo** access for a specific command to an IdM user account on a specific IdM host. First, add a **sudo** command and then create a **sudo** rule for one or more commands.

For example, complete this procedure to create the **idm_user_reboot sudo** rule to grant the **idm_user** account the permission to run the /**usr/sbin/reboot** command on the **idmclient** machine.

Prerequisites

- You are logged in as IdM administrator.
- You have created a user account for **idm_user** in IdM and unlocked the account by creating a password for the user. For details on adding a new IdM user using the CLI, see Adding users using the command line.
- No local idm_user account is present on the idmclient host. The idm_user user is not listed in the local /etc/passwd file.

Procedure

1. Retrieve a Kerberos ticket as the IdM admin.

[root@idmclient ~]# kinit admin

2. Add the /usr/sbin/reboot command to the IdM database of sudo commands:

```
[root@idmclient ~]# ipa sudocmd-add /usr/sbin/reboot
------
Added Sudo Command "/usr/sbin/reboot"
------
Sudo Command: /usr/sbin/reboot
```

3. Create a **sudo** rule named **idm_user_reboot**:

```
[root@idmclient ~]# ipa sudorule-add idm_user_reboot
-----
Added Sudo Rule "idm_user_reboot"
------
Rule name: idm_user_reboot
Enabled: TRUE
```

4. Add the /usr/sbin/reboot command to the idm_user_reboot rule:

5. Apply the idm_user_reboot rule to the IdM idmclient host:

6. Add the idm_user account to the idm_user_reboot rule:

```
[root@idmclient ~]# ipa sudorule-add-user idm_user_reboot --users idm_user
Rule name: idm_user_reboot
Enabled: TRUE
Users: idm_user
Hosts: idmclient.idm.example.com
Sudo Allow Commands: /usr/sbin/reboot
```

Number of members added 1

- 7. Optional: Define the validity of the **idm_user_reboot** rule:
 - a. To define the time at which a **sudo** rule starts to be valid, use the **ipa sudorule-mod sudo_rule_name** command with the **--setattr sudonotbefore=DATE** option. The DATE value must follow the **yyyymmddHHMMSSZ** format, with seconds specified explicitly. For example, to set the start of the validity of the **idm_user_reboot** rule to 31 December 2025 12:34:00, enter:

[root@idmclient ~]# ipa sudorule-mod idm_user_reboot --setattr sudonotbefore=20251231123400Z

b. To define the time at which a sudo rule stops being valid, use the --setattr sudonotafter=DATE option. For example, to set the end of the idm_user_reboot rule validity to 31 December 2026 12:34:00, enter:

[root@idmclient ~]# ipa sudorule-mod idm_user_reboot --setattr sudonotafter=20261231123400Z

NOTE

Propagating the changes from the server to the client can take a few minutes.

Verification

- 1. Log in to the **idmclient** host as the **idm user** account.
- 2. Display which **sudo** rules the **idm_user** account is allowed to perform.

[idm_user@idmclient ~]\$ sudo -I

Matching Defaults entries for **idm_user** on **idmclient**:

!visiblepw, always_set_home, match_group_by_gid, always_query_group_plugin, env_reset, env_keep="COLORS DISPLAY HOSTNAME HISTSIZE KDEDIR LS COLORS",

env_keep+="MAIL PS1 PS2 QTDIR USERNAME LANG LC_ADDRESS LC_CTYPE",
env_keep+="LC_COLLATE LC_IDENTIFICATION LC_MEASUREMENT
LC MESSAGES",

env_keep+="LC_MONETARY LC_NAME LC_NUMERIC LC_PAPER LC_TELEPHONE", env_keep+="LC_TIME LC_ALL LANGUAGE LINGUAS _XKB_CHARSET XAUTHORITY KRB5CCNAME",

secure_path=/sbin\:/bin\:/usr/sbin\:/usr/bin

User idm_user may run the following commands on idmclient: (root) /usr/sbin/reboot

3. Reboot the machine using **sudo**. Enter the password for **idm user** when prompted:

[idm_user@idmclient ~]\$ sudo /usr/sbin/reboot [sudo] password for idm_user:

8.3. GRANTING SUDO ACCESS TO AN AD USER ON AN IDM CLIENT USING THE CLI

Identity Management (IdM) system administrators can use IdM user groups to set access permissions, host-based access control, **sudo** rules, and other controls on IdM users. IdM user groups grant and restrict access to IdM domain resources.

You can add both {AD} (AD) users and AD groups to IdM user groups. To do that:

- 1. Add the AD users or groups to a *non-POSIX* external IdM group.
- 2. Add the non-POSIX external IdM group to an IdM POSIX group.

You can then manage the privileges of the AD users by managing the privileges of the POSIX group. For example, you can grant **sudo** access for a specific command to an IdM POSIX user group on a specific IdM host.

NOTE

It is also possible to add AD user groups as members to IdM external groups. This might make it easier to define policies for Windows users, by keeping the user and group management within the single AD realm.

IMPORTANT

Do **not** use ID overrides of AD users for SUDO rules in IdM. ID overrides of AD users represent only POSIX attributes of AD users, not AD users themselves.

You can add ID overrides as group members. However, you can only use this functionality to manage IdM resources in the IdM API. The possibility to add ID overrides as group members is not extended to POSIX environments and you therefore cannot use it for membership in **sudo** or host-based access control (HBAC) rules.

Follow this procedure to create the ad_users_reboot sudo rule to grant the administrator@addomain.com AD user the permission to run the /usr/sbin/reboot command on the idmclient IdM host, which is normally reserved for the root user. administrator@ad-domain.com is a member of the ad_users_external non-POSIX group, which is, in turn, a member of the ad_users POSIX group.

Prerequisites

- You have obtained the IdM **admin** Kerberos ticket-granting ticket (TGT).
- A cross-forest trust exists between the IdM domain and the ad-domain.com AD domain.
- No local **administrator** account is present on the **idmclient** host: the **administrator** user is not listed in the local /**etc/passwd** file.

Procedure

- Create the ad_users group that contains the ad_users_external group with the administrator@ad-domain member:
 - a. Optional: Create or select a corresponding group in the AD domain to use to manage AD users in the IdM realm. You can use multiple AD groups and add them to different groups on the IdM side.

b. Create the *ad_users_external* group and indicate that it contains members from outside the IdM domain by adding the **--external** option:

[root@ipaserver ~]# ipa group-add --desc='AD users external map' ad_users_external --external

Added group "ad_users_external"

Group name: ad_users_external Description: AD users external map

NOTE

Ensure that the external group that you specify here is an AD security group with a **global** or **universal** group scope as defined in the Active Directory security groups document. For example, the **Domain users** or **Domain admins** AD security groups cannot be used because their group scope is **domain local**.

c. Create the **ad_users** group:

[root@ipaserver ~]# ipa group-add --desc='AD users' ad_users

Added group "ad users"

Group name: ad_users Description: AD users GID: 129600004

d. Add the administrator@ad-domain.com AD user to ad_users_external as an external member:

[root@ipaserver ~]# ipa group-add-member ad_users_external --external "administrator@ad-domain.com"

[member user]:

[member group]:

Group name: ad_users_external Description: AD users external map

External member: S-1-5-21-3655990580-1375374850-1633065477-513

Number of members added 1

The AD user must be identified by a fully-qualified name, such as **DOMAIN**\user_name or user_name@DOMAIN. The AD identity is then mapped to the AD SID for the user. The same applies to adding AD groups.

e. Add ad_users_external to ad_users as a member:

[root@ipaserver ~]# ipa group-add-member ad_users --groups ad_users_external

Group name: ad_users Description: AD users GID: 129600004

Member groups: ad_users_external

Number of members added 1

- 2. Grant the members of ad users the permission to run /usr/sbin/reboot on the idmclient host:
 - a. Add the /usr/sbin/reboot command to the IdM database of sudo commands:

[root@idmclient ~]# ipa sudocmd-add /usr/sbin/reboot
-----Added Sudo Command "/usr/sbin/reboot"
-----Sudo Command: /usr/sbin/reboot

b. Create a **sudo** rule named **ad_users_reboot**:

[root@idmclient ~]# ipa sudorule-add ad_users_reboot
----Added Sudo Rule "ad_users_reboot"
----Rule name: ad_users_reboot
Enabled: True

c. Add the /usr/sbin/reboot command to the ad_users_reboot rule:

[root@idmclient ~]# ipa sudorule-add-allow-command ad_users_reboot --sudocmds
'/usr/sbin/reboot'
Rule name: ad_users_reboot
Enabled: True
Sudo Allow Commands: /usr/sbin/reboot
-----Number of members added 1

d. Apply the ad_users_reboot rule to the IdM idmclient host:

[root@idmclient ~]# ipa sudorule-add-host ad_users_reboot --hosts idmclient.idm.example.com
Rule name: ad_users_reboot

Enabled: True

Hosts: idmclient.idm.example.com Sudo Allow Commands: /usr/sbin/reboot

Number of members added 1

e. Add the **ad_users** group to the **ad_users_reboot** rule:

[root@idmclient ~]# ipa sudorule-add-user ad_users_reboot --groups ad_users

Rule name: ad_users_reboot

Enabled: TRUE

User Groups: ad_users

Hosts: idmclient.idm.example.com Sudo Allow Commands: /usr/sbin/reboot Number of members added 1

NOTE

Propagating the changes from the server to the client can take a few minutes.

Verification

 Log in to the idmclient host as administrator@ad-domain.com, an indirect member of the ad_users group:

\$ ssh administrator@ad-domain.com@ipaclient Password:

2. Optional: Display the **sudo** commands that **administrator@ad-domain.com** is allowed to execute:

[administrator@ad-domain.com@idmclient ~]\$ sudo -I

Matching Defaults entries for administrator@ad-domain.com on idmclient:

!visiblepw, always_set_home, match_group_by_gid, always_query_group_plugin,
 env_reset, env_keep="COLORS DISPLAY HOSTNAME HISTSIZE KDEDIR

LS_COLORS",
 env_keep+="MAIL PS1 PS2 QTDIR USERNAME LANG LC_ADDRESS LC_CTYPE",
 env_keep+="LC_COLLATE LC_IDENTIFICATION LC_MEASUREMENT

LC_MESSAGES",
 env_keep+="LC_MONETARY LC_NAME LC_NUMERIC LC_PAPER LC_TELEPHONE",
 env_keep+="LC_TIME LC_ALL LANGUAGE LINGUAS_XKB_CHARSET XAUTHORITY

KRB5CCNAME".

secure_path=/sbin\:/bin\:/usr/sbin\:/usr/bin

User administrator@ad-domain.com may run the following commands on idmclient: (root) /usr/sbin/reboot

3. Reboot the machine using **sudo**. Enter the password for **administrator@ad-domain.com** when prompted:

[administrator@ad-domain.com@idmclient ~]\$ **sudo** /usr/sbin/reboot [sudo] password for administrator@ad-domain.com:

Additional resources

- Active Directory users and Identity Management groups
- Include users and groups from a trusted Active Directory domain into SUDO rules

8.4. GRANTING SUDO ACCESS TO AN IDM USER ON AN IDM CLIENT USING THE IDM WEB UI

In Identity Management (IdM), you can grant **sudo** access for a specific command to an IdM user account on a specific IdM host. First, add a **sudo** command and then create a **sudo** rule for one or more commands.

Complete this procedure to create the **idm_user_reboot** sudo rule to grant the **idm_user** account the permission to run the /usr/sbin/reboot command on the **idmclient** machine.

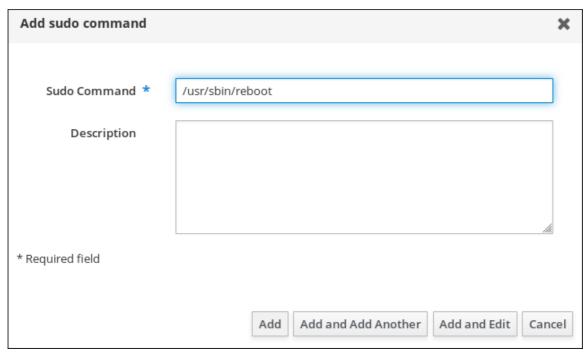

Prerequisites

- You are logged in as IdM administrator.
- You have created a user account for idm_user in IdM and unlocked the account by creating a
 password for the user. For details on adding a new IdM user using the command line, see Adding
 users using the command line.
- No local **idm_user** account is present on the **idmclient** host. The **idm_user** user is not listed in the local /etc/passwd file.

Procedure

- 1. Add the /usr/sbin/reboot command to the IdM database of sudo commands:
 - a. Navigate to Policy → Sudo → Sudo Commands.
 - b. Click **Add** in the upper right corner to open the **Add sudo command** dialog box.
 - c. Enter the command you want the user to be able to perform using **sudo**: /usr/sbin/reboot.

Figure 8.1. Adding IdM sudo command

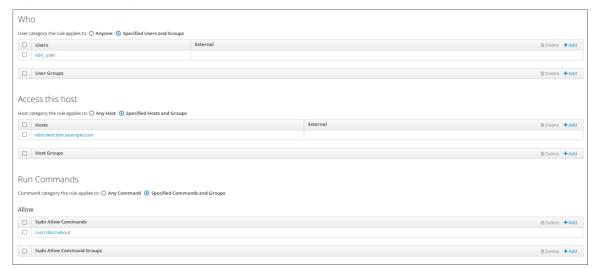

- d. Click Add.
- 2. Use the new **sudo** command entry to create a sudo rule to allow **idm_user** to reboot the **idmclient** machine:
 - a. Navigate to Policy → Sudo → Sudo rules.
 - b. Click **Add** in the upper right corner to open the **Add sudo rule** dialog box.
 - c. Enter the name of the **sudo** rule: **idm_user_reboot**.

d. Click Add and Edit

- e. Specify the user:
 - i. In the Who section, check the Specified Users and Groups radio button.
 - ii. In the **User category the rule applies to** subsection, click **Add** to open the **Add users into sudo rule "idm_user_reboot"** dialog box.
 - iii. In the Add users into sudo rule "idm_user_reboot" dialog box in the Available column, check the idm_user checkbox, and move it to the Prospective column.
 - iv. Click Add.
- f. Specify the host:
 - i. In the Access this host section, check the Specified Hosts and Groups radio button.
 - ii. In the **Host category this rule applies to** subsection, click **Add** to open the **Add hosts** into sudo rule "idm_user_reboot" dialog box.
 - iii. In the Add hosts into sudo rule "idm_user_reboot" dialog box in the Available column, check the idmclient.idm.example.com checkbox, and move it to the Prospective column.
 - iv. Click Add.
- g. Specify the commands:
 - i. In the Command category the rule applies to subsection of the Run Commands section, check the Specified Commands and Groups radio button.
 - ii. In the Sudo Allow Commands subsection, click Add to open the Add allow sudo commands into sudo rule "idm_user_reboot" dialog box.
 - iii. In the Add allow sudo commands into sudo rule "idm_user_reboot" dialog box in the Available column, check the /usr/sbin/reboot checkbox, and move it to the Prospective column.
 - iv. Click Add to return to the idm_sudo_reboot page.

Figure 8.2. Adding IdM sudo rule

h. Click Save in the top left corner.

The new rule is enabled by default.

NOTE

Propagating the changes from the server to the client can take a few minutes.

Verification

- 1. Log in to idmclient as idm user.
- 2. Reboot the machine using **sudo**. Enter the password for **idm user** when prompted:

\$ sudo /usr/sbin/reboot [sudo] password for idm_user:

If the **sudo** rule is configured correctly, the machine reboots.

8.5. CREATING A SUDO RULE ON THE CLI THAT RUNS A COMMAND AS A SERVICE ACCOUNT ON AN IDM CLIENT

In IdM, you can configure a **sudo** rule with a *RunAs alias* to run a **sudo** command as another user or group. For example, you might have an IdM client that hosts a database application, and you need to run commands as the local service account that corresponds to that application.

Use this example to create a **sudo** rule on the command line called **run_third-party-app_report** to allow the **idm_user** account to run the **/opt/third-party-app/bin/report** command as the **thirdpartyapp** service account on the **idmclient** host.

Prerequisites

- You are logged in as IdM administrator.
- You have created a user account for idm_user in IdM and unlocked the account by creating a
 password for the user. For details on adding a new IdM user using the CLI, see Adding users
 using the command line.
- No local **idm_user** account is present on the **idmclient** host. The **idm_user** user is not listed in the local /etc/passwd file.
- You have a custom application named third-party-app installed on the idmclient host.
- The **report** command for the **third-party-app** application is installed in the **/opt/third-party-app/bin/report** directory.
- You have created a local service account named thirdpartyapp to execute commands for the third-party-app application.

Procedure

1. Retrieve a Kerberos ticket as the IdM admin.

[root@idmclient ~]# kinit admin

2. Add the /opt/third-party-app/bin/report command to the IdM database of sudo commands:

```
[root@idmclient ~]# ipa sudocmd-add /opt/third-party-app/bin/report
Added Sudo Command "/opt/third-party-app/bin/report"
 Sudo Command: /opt/third-party-app/bin/report
```

3. Create a **sudo** rule named **run third-party-app report**:

```
[root@idmclient ~]# ipa sudorule-add run_third-party-app_report
Added Sudo Rule "run_third-party-app_report"
 Rule name: run_third-party-app_report
 Enabled: TRUE
```

4. Use the --users=<user> option to specify the RunAs user for the sudorule-add-runasuser command:

```
[root@idmclient ~]# ipa sudorule-add-runasuser run_third-party-app_report --
users=thirdpartyapp
 Rule name: run_third-party-app_report
 Enabled: TRUE
 RunAs External User: thirdpartyapp
Number of members added 1
-----
```

The user (or group specified with the --groups=* option) can be external to IdM, such as a local service account or an Active Directory user. Do not add a % prefix for group names.

5. Add the /opt/third-party-app/bin/report command to the run_third-party-app_report rule:

```
[root@idmclient ~]# ipa sudorule-add-allow-command run third-party-app report --
sudocmds '/opt/third-party-app/bin/report'
Rule name: run_third-party-app_report
Enabled: TRUE
Sudo Allow Commands: /opt/third-party-app/bin/report
RunAs External User: thirdpartyapp
_____
Number of members added 1
-----
```

6. Apply the run_third-party-app_report rule to the IdM idmclient host:

```
[root@idmclient ~]# ipa sudorule-add-host run_third-party-app_report --hosts
idmclient.idm.example.com
Rule name: run_third-party-app_report
```

Enabled: TRUE

Hosts: idmclient.idm.example.com

Sudo Allow Commands: /opt/third-party-app/bin/report

RunAs External User: thirdpartyapp

Number of members added 1

7. Add the idm_user account to the run_third-party-app_report rule:

[root@idmclient ~]# ipa sudorule-add-user run_third-party-app_report --users idm_user

Rule name: run_third-party-app_report

Enabled: TRUE Users: idm_user

Hosts: idmclient.idm.example.com

Sudo Allow Commands: /opt/third-party-app/bin/report

RunAs External User: thirdpartyapp

Number of members added 1

NOTE

Propagating the changes from the server to the client can take a few minutes.

Verification

- 1. Log in to the **idmclient** host as the **idm user** account.
- 2. Test the new sudo rule:
 - a. Display which **sudo** rules the **idm_user** account is allowed to perform.

[idm_user@idmclient ~]\$ **sudo -l**Matching Defaults entries for idm u

Matching Defaults entries for idm_user@idm.example.com on idmclient:

!visiblepw, always_set_home, match_group_by_gid, always_query_group_plugin, env_reset, env_keep="COLORS DISPLAY HOSTNAME HISTSIZE KDEDIR LS COLORS",

env_keep+="MAIL PS1 PS2 QTDIR USERNAME LANG LC_ADDRESS LC_CTYPE",
env_keep+="LC_COLLATE LC_IDENTIFICATION LC_MEASUREMENT

env_keep+="LC_TIME LC_ALL LANGUAGE LINGUAS _XKB_CHARSET XAUTHORITY KRB5CCNAME",

secure_path=/sbin\:/bin\:/usr/sbin\:/usr/bin

User idm_user@idm.example.com may run the following commands on idmclient: (thirdpartyapp) /opt/third-party-app/bin/report

b. Run the **report** command as the **thirdpartyapp** service account.

[idm_user@idmclient ~]\$ **sudo -u** *thirdpartyapp* /opt/third-party-app/bin/report [sudo] password for idm_user@idm.example.com:

Executing report...

Report successful.

8.6. CREATING A SUDO RULE IN THE IDM WEBUI THAT RUNS A COMMAND AS A SERVICE ACCOUNT ON AN IDM CLIENT

In IdM, you can configure a **sudo** rule with a *RunAs alias* to run a **sudo** command as another user or group. For example, you might have an IdM client that hosts a database application, and you need to run commands as the local service account that corresponds to that application.

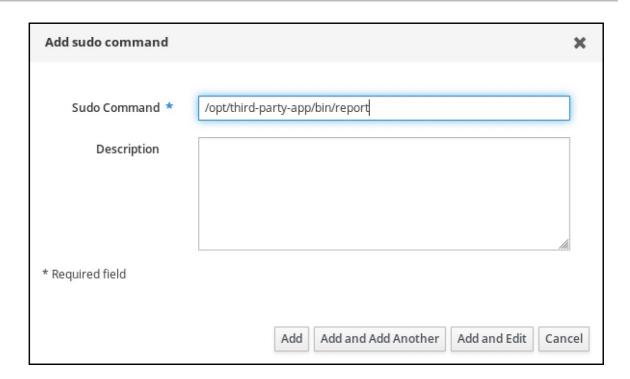

Use this example to create a **sudo** rule in the IdM WebUI called **run_third-party-app_report** to allow the **idm_user** account to run the **/opt/third-party-app/bin/report** command as the **thirdpartyapp** service account on the **idmclient** host.

Prerequisites

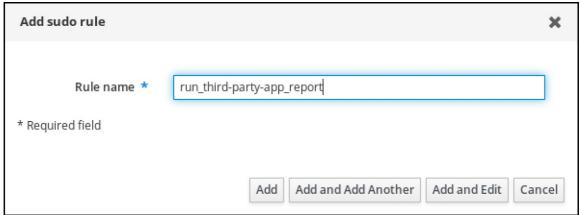

- You are logged in as IdM administrator.
- You have created a user account for idm_user in IdM and unlocked the account by creating a
 password for the user. For details on adding a new IdM user using the CLI, see Adding users
 using the command line.
- No local **idm_user** account is present on the **idmclient** host. The **idm_user** user is not listed in the local /etc/passwd file.
- You have a custom application named **third-party-app** installed on the **idmclient** host.
- The **report** command for the **third-party-app** application is installed in the **/opt/third-party-app/bin/report** directory.
- You have created a local service account named **thirdpartyapp** to execute commands for the **third-party-app** application.

Procedure

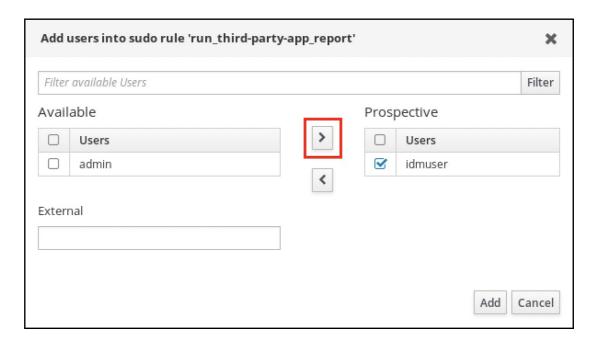

- 1. Add the /opt/third-party-app/bin/report command to the IdM database of sudo commands:
 - a. Navigate to **Policy** → **Sudo** → **Sudo** Commands.
 - b. Click Add in the upper right corner to open the Add sudo command dialog box.
 - c. Enter the command: /opt/third-party-app/bin/report.

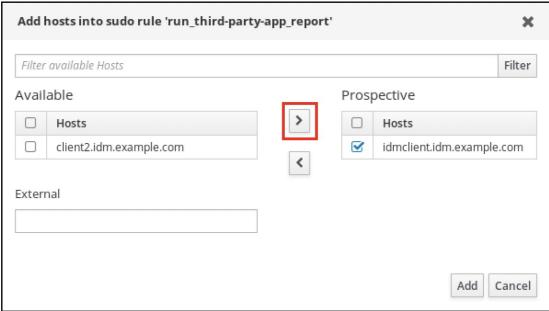

- d. Click Add.
- 2. Use the new **sudo** command entry to create the new **sudo** rule:
 - a. Navigate to Policy → Sudo → Sudo rules.
 - b. Click **Add** in the upper right corner to open the **Add sudo rule** dialog box.
 - c. Enter the name of the **sudo** rule: run_third-party-app_report.

- d. Click Add and Edit
- e. Specify the user:
 - i. In the **Who** section, check the **Specified Users and Groups** radio button.
 - ii. In the **User category the rule applies to** subsection, click **Add** to open the **Add users into sudo rule "run_third-party-app_report"** dialog box.
 - iii. In the Add users into sudo rule "run_third-party-app_report" dialog box in the Available column, check the idm_user checkbox, and move it to the Prospective column.

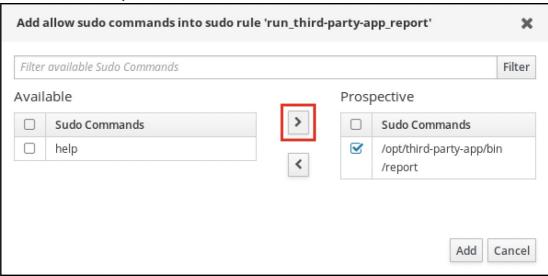

- iv. Click Add.
- f. Specify the host:
 - i. In the Access this host section, check the Specified Hosts and Groups radio button.
 - ii. In the **Host category this rule applies to** subsection, click **Add** to open the **Add hosts** into sudo rule "run_third-party-app_report" dialog box.
 - iii. In the Add hosts into sudo rule "run_third-party-app_report" dialog box in the Available column, check the idmclient.idm.example.com checkbox, and move it to the Prospective column.

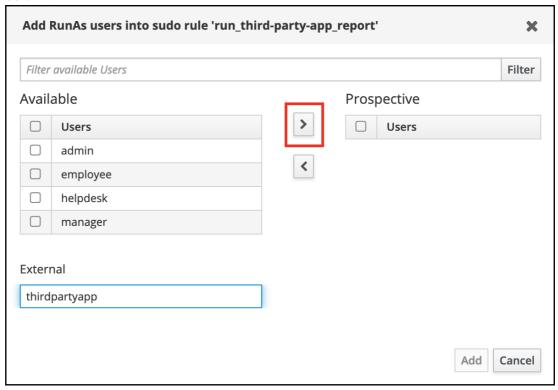

- iv. Click Add.
- g. Specify the commands:
 - i. In the Command category the rule applies to subsection of the Run Commands section, check the Specified Commands and Groups radio button.

- ii. In the **Sudo Allow Commands** subsection, click **Add** to open the **Add allow sudo commands into sudo rule "run_third-party-app_report"** dialog box.
- iii. In the Add allow sudo commands into sudo rule "run_third-party-app_report" dialog box in the Available column, check the /opt/third-party-app/bin/report checkbox, and move it to the Prospective column.

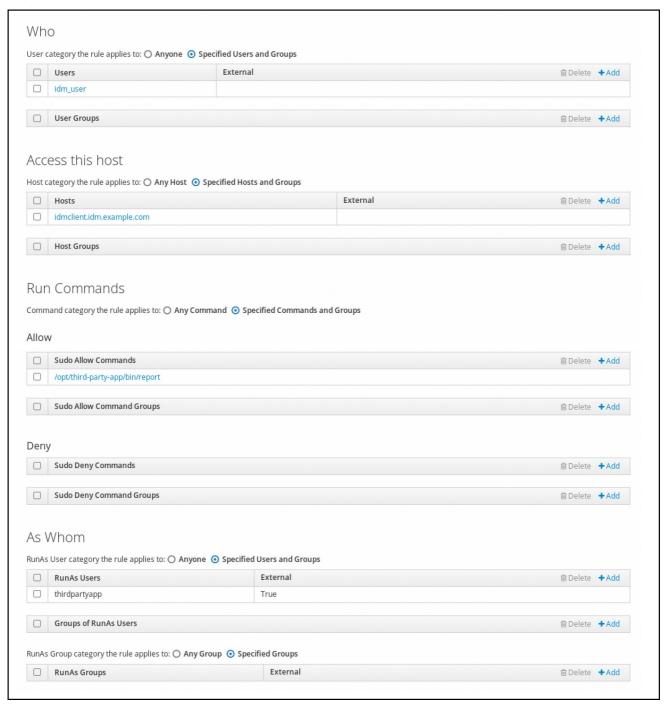

- iv. Click Add to return to the run_third-party-app_report page.
- h. Specify the RunAs user:
 - i. In the As Whom section, check the Specified Users and Groups radio button.
 - ii. In the RunAs Users subsection, click Add to open the Add RunAs users into sudo rule "run_third-party-app_report" dialog box.
 - iii. In the Add RunAs users into sudo rule "run_third-party-app_report" dialog box, enter the **thirdpartyapp** service account in the **External** box and move it to the **Prospective** column.

- iv. Click Add to return to the run_third-party-app_report page.
- i. Click **Save** in the top left corner.

The new rule is enabled by default.

Figure 8.3. Details of the sudo rule

NOTE

Propagating the changes from the server to the client can take a few minutes.

Verification

- 1. Log in to the **idmclient** host as the **idm_user** account.
- 2. Test the new sudo rule:

a. Display which **sudo** rules the **idm_user** account is allowed to perform.

```
[idm_user@idmclient ~]$ sudo -I

Matching Defaults entries for idm_user@idm.example.com on idmclient:
    !visiblepw, always_set_home, match_group_by_gid, always_query_group_plugin,
    env_reset, env_keep="COLORS DISPLAY HOSTNAME HISTSIZE KDEDIR

LS_COLORS",
    env_keep+="MAIL PS1 PS2 QTDIR USERNAME LANG LC_ADDRESS LC_CTYPE",
    env_keep+="LC_COLLATE LC_IDENTIFICATION LC_MEASUREMENT

LC_MESSAGES",
    env_keep+="LC_MONETARY LC_NAME LC_NUMERIC LC_PAPER

LC_TELEPHONE",
    env_keep+="LC_TIME LC_ALL LANGUAGE LINGUAS_XKB_CHARSET

XAUTHORITY KRB5CCNAME",
    secure_path=/sbin\:/bin\:/usr/sbin\:/usr/bin
```

User idm_user@idm.example.com may run the following commands on idmclient: (thirdpartyapp) /opt/third-party-app/bin/report

b. Run the **report** command as the **thirdpartyapp** service account.

[idm_user@idmclient ~]\$ **sudo -u** *thirdpartyapp* /opt/third-party-app/bin/report [sudo] password for idm_user@idm.example.com:
Executing report...
Report successful.

8.7. ENABLING GSSAPI AUTHENTICATION FOR SUDO ON AN IDM CLIENT

Enable Generic Security Service Application Program Interface (GSSAPI) authentication on an IdM client for the **sudo** and **sudo -i** commands via the **pam_sss_gss.so** PAM module. With this configuration, IdM users can authenticate to the **sudo** command with their Kerberos ticket.

Prerequisites

- You have created a **sudo** rule for an IdM user that applies to an IdM host. For this example, you
 have created the **idm_user_reboot sudo** rule to grant the **idm_user** account the permission to
 run the /usr/sbin/reboot command on the **idmclient** host.
- You need root privileges to modify the /etc/sssd/sssd.conf file and PAM files in the /etc/pam.d/ directory.

Procedure

- 1. Open the /etc/sssd/sssd.conf configuration file.

```
[domain/<domain_name>]
pam_gssapi_services = sudo, sudo-i
```

- 3. Save and close the /etc/sssd/sssd.conf file.
- 4. Restart the SSSD service to load the configuration changes.

[root@idmclient ~]# systemctl restart sssd

5. Optional: Determine if you have selected the **sssd authselect** profile:

authselect current

Profile ID: sssd

6. If the **sssd authselect** profile is selected, enable GSSAPI authentication:

authselect enable-feature with-gssapi

7. If the **sssd authselect** profile is not selected, select it and enable GSSAPI authentication:

authselect select sssd with-gssapi

Verification

1. Log into the host as the **idm user** account.

[root@idm-client ~]# **ssh -l** *idm_user@idm.example.com* **localhost** idm_user@idm.example.com's password:

2. Verify that you have a ticket-granting ticket as the **idm user** account.

[idmuser@idmclient ~]\$ klist

Ticket cache: KCM:1366201107

Default principal: idm_user@IDM.EXAMPLE.COM

Valid starting Expires Service principal

01/08/2021 09:11:48 01/08/2021 19:11:48

krbtgt/IDM.EXAMPLE.COM@IDM.EXAMPLE.COM

renew until 01/15/2021 09:11:44

3. Optional: If you do not have Kerberos credentials for the **idm_user** account, delete your current Kerberos credentials and request the correct ones.

[idm_user@idmclient ~]\$ kdestroy -A

[idm_user@idmclient ~]\$ kinit idm_user@IDM.EXAMPLE.COM Password for idm_user@idm.example.com:

4. Reboot the machine using **sudo**, without specifying a password.

[idm_user@idmclient ~]\$ sudo /usr/sbin/reboot

Additional resources

- The GSSAPI entry in the IdM terminology listing
- Granting sudo access to an IdM user on an IdM client using IdM Web UI
- Granting sudo access to an IdM user on an IdM client using the CLI

pam_sss_gss (8) and sssd.conf (5) man pages on your system

8.8. ENABLING GSSAPI AUTHENTICATION AND ENFORCING KERBEROS AUTHENTICATION INDICATORS FOR SUDO ON AN IDM CLIENT

Enable Generic Security Service Application Program Interface (GSSAPI) authentication on an IdM client for the **sudo** and **sudo -i** commands via the **pam_sss_gss.so** PAM module. Additionally, only users who have logged in with a smart card will authenticate to those commands with their Kerberos ticket.

NOTE

You can use this procedure as a template to configure GSSAPI authentication with SSSD for other PAM-aware services, and further restrict access to only those users that have a specific authentication indicator attached to their Kerberos ticket.

Prerequisites

- You have created a **sudo** rule for an IdM user that applies to an IdM host. For this example, you have created the **idm_user_reboot sudo** rule to grant the **idm_user** account the permission to run the /usr/sbin/reboot command on the **idmclient** host.
- You have configured smart card authentication for the **idmclient** host.
- You need **root** privileges to modify the /etc/sssd/sssd.conf file and PAM files in the /etc/pam.d/ directory.

Procedure

- 1. Open the /etc/sssd/sssd.conf configuration file.
- 2. Add the following entries to the **[domain/**domain_name] section.

```
[domain/<domain_name>]
pam_gssapi_services = sudo, sudo-i
pam_gssapi_indicators_map = sudo:pkinit, sudo-i:pkinit
```

- 3. Save and close the /etc/sssd/sssd.conf file.
- 4. Restart the SSSD service to load the configuration changes.
 - [root@idmclient ~]# systemctl restart sssd
- 5. Determine if you have selected the **sssd authselect** profile:

authselect current Profile ID: sssd

6. Optional: Select the **sssd authselect** profile:

authselect select sssd

7. Enable GSSAPI authentication:

authselect enable-feature with-gssapi

8. Configure the system to authenticate only users with smart cards:

authselect with-smartcard-required

Verification

1. Log into the host as the **idm_user** account and authenticate with a smart card.

[root@idmclient ~]# ssh -l idm_user@idm.example.com localhost PIN for smart_card

2. Verify that you have a ticket-granting ticket as the smart card user.

[idm_user@idmclient ~]\$ klist

Ticket cache: KEYRING:persistent:1358900015:krb_cache_TObtNMd

Default principal: idm user@IDM.EXAMPLE.COM

Valid starting Expires Service principal 02/15/2021 16:29:48 02/16/2021 02:29:48 krbtgt/IDM.EXAMPLE.COM@IDM.EXAMPLE.COM renew until 02/22/2021 16:29:44

3. Display which **sudo** rules the **idm_user** account is allowed to perform.

[idm_user@idmclient ~]\$ sudo -I

Matching Defaults entries for **idmuser** on **idmclient**:

!visiblepw, always_set_home, match_group_by_gid, always_query_group_plugin, env_reset, env_keep="COLORS DISPLAY HOSTNAME HISTSIZE KDEDIR LS COLORS",

env_keep+="MAIL PS1 PS2 QTDIR USERNAME LANG LC_ADDRESS LC_CTYPE", env_keep+="LC_COLLATE LC_IDENTIFICATION LC_MEASUREMENT LC MESSAGES",

env_keep+="LC_MONETARY LC_NAME LC_NUMERIC LC_PAPER LC_TELEPHONE", env_keep+="LC_TIME LC_ALL LANGUAGE LINGUAS _XKB_CHARSET XAUTHORITY KRB5CCNAME",

secure_path=/sbin\:/bin\:/usr/sbin\:/usr/bin

User idm_user may run the following commands on idmclient: (root) /usr/sbin/reboot

4. Reboot the machine using **sudo**, without specifying a password.

[idm_user@idmclient ~]\$ sudo /usr/sbin/reboot

Additional resources

- SSSD options controlling GSSAPI authentication for PAM services
- The GSSAPI entry in the IdM terminology listing

- Configuring Identity Management for smart card authentication
- Granting sudo access to an IdM user on an IdM client using IdM Web UI
- Granting sudo access to an IdM user on an IdM client using the CLI .
- pam_sss_gss (8) and sssd.conf (5) man pages on your system

8.9. SSSD OPTIONS CONTROLLING GSSAPI AUTHENTICATION FOR PAM SERVICES

You can use the following options for the /etc/sssd/sssd.conf configuration file to adjust the GSSAPI configuration within the SSSD service.

pam_gssapi_services

GSSAPI authentication with SSSD is disabled by default. You can use this option to specify a comma-separated list of PAM services that are allowed to try GSSAPI authentication using the **pam_sss_gss.so** PAM module. To explicitly disable GSSAPI authentication, set this option to -.

pam_gssapi_indicators_map

This option only applies to Identity Management (IdM) domains. Use this option to list Kerberos authentication indicators that are required to grant PAM access to a service. Pairs must be in the format *PAM_service*:_<required_authentication_indicator>_.

Valid authentication indicators are:

- **otp** for two-factor authentication
- radius for RADIUS authentication
- **pkinit** for PKINIT, smart card, or certificate authentication
- **hardened** for hardened passwords

pam_gssapi_check_upn

This option is enabled and set to **true** by default. If this option is enabled, the SSSD service requires that the user name matches the Kerberos credentials. If **false**, the **pam_sss_gss.so** PAM module authenticates every user that is able to obtain the required service ticket.

Examples

The following options enable Kerberos authentication for the **sudo** and **sudo-i** services, requires that **sudo** users authenticated with a one-time password, and user names must match the Kerberos principal. Because these settings are in the `` section, they apply to all domains:

```
[pam]
pam_gssapi_services = sudo, sudo-i
pam_gssapi_indicators_map = sudo:otp
pam_gssapi_check_upn = true
```

You can also set these options in individual **sections to overwrite any global values in the** section. The following options apply different GSSAPI settings to each domain:

For the idm.example.com domain

• Enable GSSAPI authentication for the **sudo** and **sudo -i** services.

- Require certificate or smart card authentication authenticators for the **sudo** command.
- Require one-time password authentication authenticators for the **sudo -i** command.
- Enforce matching user names and Kerberos principals.

For the ad.example.com domain

- Enable GSSAPI authentication only for the sudo service.
- Do not enforce matching user names and principals.

```
[domain/idm.example.com]

pam_gssapi_services = sudo, sudo-i

pam_gssapi_indicators_map = sudo:pkinit, sudo-i:otp

pam_gssapi_check_upn = true
...

[domain/ad.example.com]

pam_gssapi_services = sudo

pam_gssapi_check_upn = false
...
```

8.10. TROUBLESHOOTING GSSAPI AUTHENTICATION FOR SUDO

If you are unable to authenticate to the **sudo** service with a Kerberos ticket from IdM, use the following scenarios to troubleshoot your configuration.

Prerequisites

- You have enabled GSSAPI authentication for the **sudo** service. See Enabling GSSAPI authentication for sudo on an IdM client.
- You need **root** privileges to modify the /etc/sssd/sssd.conf file and PAM files in the /etc/pam.d/ directory.

Procedure

• If you see the following error, the Kerberos service might not able to resolve the correct realm for the service ticket based on the host name:

Server not found in Kerberos database

In this situation, add the hostname directly to **[domain_realm]** section in the /etc/krb5.conf Kerberos configuration file:

```
[idm-user@idm-client ~]$ cat /etc/krb5.conf ...

[domain_realm]
.example.com = EXAMPLE.COM
example.com = EXAMPLE.COM
server.example.com = EXAMPLE.COM
```

• If you see the following error, you do not have any Kerberos credentials:

No Kerberos credentials available

In this situation, retrieve Kerberos credentials with the **kinit** utility or authenticate with SSSD:

[idm-user@idm-client ~]\$ kinit idm-user@IDM.EXAMPLE.COM Password for idm-user@idm.example.com:

• If you see either of the following errors in the /var/log/sssd/sssd_pam.log log file, the Kerberos credentials do not match the username of the user currently logged in:

User with UPN [<UPN>] was not found.

UPN [<UPN>] does not match target user [<username>].

In this situation, verify that you authenticated with SSSD, or consider disabling the **pam_gssapi_check_upn** option in the /**etc/sssd/sssd.conf** file:

```
[idm-user@idm-client ~]$ cat /etc/sssd/sssd.conf
...
pam_gssapi_check_upn = false
```

- For additional troubleshooting, you can enable debugging output for the **pam_sss_gss.so** PAM module.
 - Add the **debug** option at the end of all **pam_sss_gss.so** entries in PAM files, such as /etc/pam.d/sudo and /etc/pam.d/sudo-i:

```
[root@idm-client ~]# cat /etc/pam.d/sudo
#%PAM-1.0
auth sufficient pam_sss_gss.so debug
auth include system-auth
account include system-auth
password include system-auth
session include system-auth
```

```
[root@idm-client ~]# cat /etc/pam.d/sudo-i
#%PAM-1.0
auth sufficient pam_sss_gss.so debug
auth include sudo
account include sudo
password include sudo
session optional pam_keyinit.so force revoke
session include sudo
```

• Try to authenticate with the **pam_sss_gss.so** module and review the console output. In this example, the user did not have any Kerberos credentials.

```
[idm-user@idm-client ~]$ sudo Is -I /etc/sssd/sssd.conf
pam_sss_gss: Initializing GSSAPI authentication with SSSD

8.11. ADDITIONAL RESOURCES

- Using an Ansible playbook to ensure sudo access for an IdM user on an IdM client
- Managing multiple IdM sudo rules in a single Ansible task

CHAPTER 9. USING LDAPMODIFY TO MANAGE IDM USERS EXTERNALLY

As an IdM administrators you can use the **ipa** commands to manage your directory content. Alternatively, you can use the **Idapmodify** command to achieve similar goals. You can use this command interactively and provide all the data directly in the command line. You also can provide data in the file in the LDAP Data Interchange Format (LDIF) to **Idapmodify** command.

9.1. TEMPLATES FOR MANAGING IDM USER ACCOUNTS EXTERNALLY

The following templates can be used for various user management operations in IdM. The templates show which attributes you must modify using **Idapmodify** to achieve the following goals:

- Adding a new stage user
- Modifying a user's attribute
- Enabling a user
- Disabling a user
- Preserving a user

The templates are formatted in the LDAP Data Interchange Format (LDIF). LDIF is a standard plain text data interchange format for representing LDAP directory content and update requests.

Using the templates, you can configure the LDAP provider of your provisioning system to manage IdM user accounts.

For detailed example procedures, see the following sections:

- Adding an IdM stage user defined in an LDIF file
- Adding an IdM stage user directly from the CLI using Idapmodify
- Preserving an IdM user with Idapmodify

Templates for adding a new stage user

• A template for adding a user with **UID** and **GID** assigned automatically. The distinguished name (DN) of the created entry must start with **uid=user login**:

dn: uid=user login,cn=staged

users,cn=accounts,cn=provisioning,dc=idm,dc=example,dc=com

changetype: add objectClass: top

objectClass: inetorgperson

uid: user_login sn: surname

givenName: first_name

cn: full_name

• A template for adding a user with **UID** and **GID** assigned statically

dn: uid=user_login,cn=staged

users,cn=accounts,cn=provisioning,dc=idm,dc=example,dc=com

changetype: add objectClass: top objectClass: person

objectClass: inetorgperson

objectClass: organizationalperson

objectClass: posixaccount

uid: user_login

uidNumber: UID_number gidNumber: GID_number

sn: surname

givenName: first_name

cn: full_name

homeDirectory: /home/user_login

You are not required to specify any IdM object classes when adding stage users. IdM adds these classes automatically after the users are activated.

Templates for modifying existing users

• Modifying a user's attribute

dn: distinguished_name changetype: modify

replace: attribute_to_modify attribute_to_modify: new_value

• Disabling a user:

dn: distinguished_name changetype: modify replace: nsAccountLock nsAccountLock: TRUE

Enabling a user.

dn: distinguished_name changetype: modify replace: nsAccountLock nsAccountLock: FALSE

Updating the **nssAccountLock** attribute has no effect on stage and preserved users. Even though the update operation completes successfully, the attribute value remains

nssAccountLock: TRUE.

Preserving a user.

dn: distinguished_name changetype: modrdn newrdn: uid=user_login

deleteoldrdn: 0

newsuperior: cn=deleted users,cn=accounts,cn=provisioning,dc=idm,dc=example,dc=com

NOTE

Before modifying a user, obtain the user's distinguished name (DN) by searching using the user's login. In the following example, the user_allowed_to_modify_user_entries user is a user allowed to modify user and group information, for example activator or IdM administrator. The password in the example is this user's password:

Idapsearch -LLL -x -D

"uid=user_allowed_to_modify_user_entries,cn=users,cn=accounts,dc=idm,dc=e xample,dc=com" -w "Secret123" -H Idap://r8server.idm.example.com -b "cn=users,cn=accounts,dc=idm,dc=example,dc=com" uid=test_user dn: uid=test_user,cn=users,cn=accounts,dc=idm,dc=example,dc=com memberOf: cn=ipausers,cn=groups,cn=accounts,dc=idm,dc=example,dc=com

9.2. TEMPLATES FOR MANAGING IDM GROUP ACCOUNTS EXTERNALLY

The following templates can be used for various user group management operations in IdM. The templates show which attributes you must modify using **Idapmodify** to achieve the following aims:

- Creating a new group
- Deleting an existing group
- Adding a member to a group
- Removing a member from a group

The templates are formatted in the LDAP Data Interchange Format (LDIF). LDIF is a standard plain text data interchange format for representing LDAP directory content and update requests.

Using the templates, you can configure the LDAP provider of your provisioning system to manage IdM group accounts.

Creating a new group

dn: cn=group_name,cn=groups,cn=accounts,dc=idm,dc=example,dc=com

changetype: add objectClass: top objectClass: ipaobject objectClass: ipausergroup objectClass: groupofnames objectClass: nestedgroup objectClass: posixgroup

uid: group_name cn: group_name

gidNumber: GID_number

Modifying groups

Deleting an existing group:

dn: group_distinguished_name
changetype: delete

• Adding a member to a group

dn: group distinguished name

changetype: modify add: member

member: uid=user_login,cn=users,cn=accounts,dc=idm,dc=example,dc=com

Do not add stage or preserved users to groups. Even though the update operation completes successfully, the users will not be updated as members of the group. Only active users can belong to groups.

Removing a member from a group.

dn: distinguished_name changetype: modify delete: member

member: uid=user_login,cn=users,cn=accounts,dc=idm,dc=example,dc=com

Before modifying a group, obtain the group's distinguished name (DN) by searching using the group's name.

Idapsearch -YGSSAPI -H Idap://<server.idm.example.com> -b
"<cn=groups,cn=accounts,dc=idm,dc=example,dc=com>" "cn=<group_name>"

dn: cn=group_name,cn=groups,cn=accounts,dc=idm,dc=example,dc=comipaNTSecurityIdentifier: S-1-5-21-1650388524-2605035987-2578146103-11017

cn: testgroup objectClass: top

objectClass: groupofnames objectClass: nestedgroup objectClass: ipausergroup objectClass: ipaobject objectClass: posixgroup objectClass: ipantgroupattrs

ipaUniqueID: 569bf864-9d45-11ea-bea3-525400f6f085

gidNumber: 1997010017

9.3. USING LDAPMODIFY COMMAND INTERACTIVELY

You can modify Lightweight Directory Access Protocol (LDAP) entries in the interactive mode.

Procedure

1. In a command line, enter the LDAP Data Interchange Format (LDIF) statement after the **Idapmodify** command.

Example 9.1. Changing the telephone number for atestuser

Idapmodify -Y GSSAPI -H Idap://<server.example.com>

dn: uid=testuser,cn=users,cn=accounts,dc=example,dc=com

changetype: modify

replace: telephoneNumber telephonenumber: 88888888

Note that you need to obtain a Kerberos ticket for using **-Y** option.

- 2. Press Ctlr+D to exit the interactive mode.
- 3. Alternatively, provide an LDIF file after **Idapmodify** command:

Example 9.2. The Idapmodify command reads modification data from an LDIF file

Idapmodify -Y GSSAPI -H Idap://<server.example.com> -f ~/example.ldif

Additional resources

- For more information about how to use the **Idapmodify** command see **Idapmodify(1)** man page on your system.
- For more information about the **LDIF** structure, see **Idif(5)** man page on your system.

9.4. PRESERVING AN IDM USER WITH LDAPMODIFY

You can use **Idapmodify** to preserve an IdM user; that is, how to deactivate a user account after the employee has left the company.

Prerequisites

• You can authenticate as an IdM user with a role to preserve users.

Procedure

1. Log in as an IdM user with a role to preserve users:

\$ kinit admin

2. Enter the **Idapmodify** command and specify the Generic Security Services API (GSSAPI) as the Simple Authentication and Security Layer (SASL) mechanism to be used for authentication:

Idapmodify -Y GSSAPI

SASL/GSSAPI authentication started

SASL username: admin@IDM.EXAMPLE.COM

SASL SSF: 256

SASL data security layer installed.

3. Enter the **dn** of the user you want to preserve:

dn: uid=user1,cn=users,cn=accounts,dc=idm,dc=example,dc=com

4. Enter **modrdn** as the type of change you want to perform:

changetype: modrdn

5. Specify the **newrdn** for the user:

newrdn: uid=user1

6. Indicate that you want to preserve the user:

deleteoldrdn: 0

7. Specify the **new superior DN**:

newsuperior: cn=deleted users,cn=accounts,cn=provisioning,dc=idm,dc=example,dc=com

Preserving a user moves the entry to a new location in the directory information tree (DIT). For this reason, you must specify the DN of the new parent entry as the new superior DN.

8. Press **Enter** again to confirm that this is the end of the entry:

[Enter]

modifying rdn of entry "uid=user1,cn=users,cn=accounts,dc=idm,dc=example,dc=com"

9. Exit the connection using Ctrl + C.

Verification

• Verify that the user has been preserved by listing all preserved users:

\$ ipa user-find --preserved=true

1 user matched

-----User login: user1

First name: First 1 Last name: Last 1

Home directory: /home/user1

Login shell: /bin/sh

Principal name: user1@IDM.EXAMPLE.COM Principal alias: user1@IDM.EXAMPLE.COM Email address: user1@idm.example.com

UID: 1997010003 GID: 1997010003 Account disabled: True Preserved user: True

Number of entries returned 1

CHAPTER 10. SEARCHING IDM ENTRIES USING THE LDAPSEARCH COMMAND

You can use the **ipa find** command to search through the Identity Management entries. For more information about **ipa** command see Structure of IPA commands section in the Accessing Identity Management services documentation.

This section introduces the basics of an alternative search option using **Idapsearch** command line command through the Identity Management entries.

10.1. USING THE LDAPSEARCH COMMAND

The **Idapsearch** command has the following format:

Idapsearch [-x | -Y mechanism] [options] [search_filter] [list_of_attributes]

- To configure the authentication method, specify the **-x** option to use simple binds or the **-Y** option to set the Simple Authentication and Security Layer (SASL) mechanism. Note that you need to obtain a Kerberos ticket if you are using the **-Y GSSAPI** option.
- The options are the **Idapsearch** command options described in a table below.
- The search_filter is an LDAP search filter.
- The *list of attributes* is a list of the attributes that the search results return.

For example, you want to search all the entries of a base LDAP tree for the user name user01:

Idapsearch -x -H Idap://Idap.example.com -s sub "(uid=user01)"

- The **-x** option tells the **Idapsearch** command to authenticate with the simple bind. Note that if you do not provide the Distinguish Name (DN) with the **-D** option, the authentication is anonymous.
- The **-H** option connects you to the *Idap://Idap.example.com*.
- The **-s sub** option tells the **Idapsearch** command to search all the entries, starting from the base DN, for the user with the name user01. The "(uid=user01)" is a filter.

Note that if you do not provide the starting point for the search with the **-b** option, the command searches in the default tree. It is specified in the BASE parameter of the **etc/openIdap/Idap.conf** file.

Table 10.1. The Idapsearch command options

Option	Description
-b	The starting point for the search. If your search parameters contain an asterisk (*) or other character, that the command line can interpret into a code, you must wrap the value in single or double quotation marks. For example, -b cn=user,ou=Product Development,dc=example,dc=com.

Option	Description
-D	The Distinguished Name (DN) with which you want to authenticate.
-H	An LDAP URL to connect to the server. The -H option replaces the -h and -p options.
-I	The time limit in seconds to wait for a search request to complete.
-s scope	 The scope of the search. You can choose one of the following for the scope: base searches only the entry from the-b option or defined by the LDAP_BASEDN environment variable. one searches only the children of the entry from the -b option. sub a subtree search from the -b option starting point.
-W	Requests for the password.
-X	Disables the default SASL connection to allow simple binds.
-Y SASL_mechanism	Sets the SASL mechanism for the authentication.
-z number	The maximum number of entries in the search result.

Note, you must specify one of the authentication mechanisms with the -x or -y option with the **Idapsearch** command.

Additional resources

• For details on how to use **Idapsearch**, see **Idapsearch(1)** man page on your system.

10.2. USING THE LDAPSEARCH FILTERS

The **Idapsearch** filters allow you to narrow down the search results.

For example, you want the search result to contain all the entries with a common names set to example:

"(cn=example)"

In this case, the equal sign (=) is the operator, and example is the value.

Table 10.2. The **Idapsearch** filter operators

Search type	Operator	Description
Equality	=	Returns the entries with the exact match to the value. For example, cn=example.
Substring	=string* string	Returns all entries with the substring match. For example, cn=exa*l. The asterisk (*) indicates zero (0) or more characters.
Greater than or equal to	>=	Returns all entries with attributes that are greater than or equal to the value. For example, <i>uidNumber</i> >= 5000.
Less than or equal to	<=	Returns all entries with attributes that are less than or equal to the value. For example, <i>uidNumber</i> <= 5000.
Presence	=*	Returns all entries with one or more attributes. For example, cn=*.
Approximate	~=	Returns all entries with the similar to the value attributes. For example, <i>l</i> ~=san fransico can return <i>l</i> =san francisco.

You can use boolean operators to combine multiple filters to the <code>ldapsearch</code> command.

Table 10.3. The **Idapsearch** filter boolean operators

Search type	Operator	Description
AND	&	Returns all entries where all statements in the filters are true. For example, (&(filter)(filter) (filter)).
OR		Returns all entries where at least one statement in the filters is true. For example, ((filter)(filter)(filter)).

Search type	Operator	Description
NOT	!	Returns all entries where the statement in the filter is not true. For example, (!(filter)).

10.3. ADDITIONAL RESOURCES

• Searching entries and tuning searches in RHDS

CHAPTER 11. CONFIGURING IDM FOR EXTERNAL PROVISIONING OF USERS

As a system administrator, you can configure Identity Management (IdM) to support the provisioning of users by an external solution for managing identities.

Rather than use the **ipa** utility, the administrator of the external provisioning system can access the IdM LDAP using the **Idapmodify** utility. The administrator can add individual stage users from the CLI using Idapmodify or using an LDIF file.

The assumption is that you, as an IdM administrator, fully trust your external provisioning system to only add validated users. However, at the same time you do not want to assign the administrators of the external provisioning system the IdM role of **User Administrator** to enable them to add new active users directly.

You can configure a script to automatically move the staged users created by the external provisioning system to active users automatically.

11.1. PREPARING IDM ACCOUNTS FOR AUTOMATIC ACTIVATION OF STAGE USER ACCOUNTS

This procedure shows how to configure two IdM user accounts to be used by an external provisioning system. By adding the accounts to a group with an appropriate password policy, you enable the external provisioning system to manage user provisioning in IdM. In the following, the user account to be used by the external system to add stage users is named **provisionator**. The user account to be used to automatically activate the stage users is named **activator**.

Prerequisites

The host on which you perform the procedure is enrolled into IdM.

Procedure

- 1. Log in as IdM administrator:
 - \$ kinit admin
- 2. Create a user named **provisionator** with the privileges to add stage users.
 - a. Add the provisionator user account:
 - \$ ipa user-add provisionator --first=provisioning --last=account --password
 - b. Grant the provisionator user the required privileges.
 - i. Create a custom role, **System Provisioning**, to manage adding stage users:
 - \$ ipa role-add --desc "Responsible for provisioning stage users" "System Provisioning"
 - ii. Add the **Stage User Provisioning** privilege to the role. This privilege provides the ability to add stage users:

\$ ipa role-add-privilege "System Provisioning" --privileges="Stage User Provisioning"

iii. Add the provisionator user to the role:

\$ ipa role-add-member --users=provisionator "System Provisioning"

iv. Verify that the provisionator exists in IdM:

\$ ipa user-find provisionator --all --raw

1 user matched
-----dn: uid=provisionator,cn=users,cn=accounts,dc=idm,dc=example,dc=com uid: provisionator
...

- 3. Create a user, **activator**, with the privileges to manage user accounts.
 - a. Add the activator user account:

\$ ipa user-add activator --first=activation --last=account --password

- b. Grant the activator user the required privileges by adding the user to the default **User Administrator** role:
 - \$ ipa role-add-member --users=activator "User Administrator"
- 4. Create a user group for application accounts:
 - \$ ipa group-add application-accounts
- 5. Update the password policy for the group. The following policy prevents password expiration and lockout for the account but compensates the potential risks by requiring complex passwords:

\$ ipa pwpolicy-add application-accounts --maxlife=10000 --minlife=0 --history=0 --minclasses=4 --minlength=8 --priority=1 --maxfail=0 --failinterval=1 --lockouttime=0

6. Optional: Verify that the password policy exists in IdM:

\$ ipa pwpolicy-show application-accounts
Group: application-accounts
Max lifetime (days): 10000
Min lifetime (hours): 0
History size: 0

...

7. Add the provisioning and activation accounts to the group for application accounts:

\$ ipa group-add-member application-accounts --users={provisionator,activator}

8. Change the passwords for the user accounts:

\$ kpasswd provisionator

\$ kpasswd activator

Changing the passwords is necessary because new IdM users passwords expire immediately.

Additional resources

- Managing user accounts using the command line .
- Delegating permissions to user groups to manage users using IdM CLI.
- Defining IdM Password Policies

11.2. CONFIGURING AUTOMATIC ACTIVATION OF IDM STAGE USER ACCOUNTS

You can create a script to activate stage users. The system runs the script automatically at specified time intervals. This ensures that new user accounts are automatically activated and available for use shortly after they are created.

IMPORTANT

It is assumed that the owner of the external provisioning system has already validated the users and that they do not require additional validation on the IdM side before the script adds them to IdM.

It is sufficient to enable the activation process on only one of your IdM servers.

Prerequisites

- The **provisionator** and **activator** accounts exist in IdM. For details, see Preparing IdM accounts for automatic activation of stage user accounts.
- You have root privileges on the IdM server on which you are running the procedure.
- You are logged in as IdM administrator.
- You trust your external provisioning system.

Procedure

1. Generate a keytab file for the activation account:

ipa-getkeytab -s server.idm.example.com -p "activator" -k /etc/krb5.ipa-activation.keytab

If you want to enable the activation process on more than one IdM server, generate the keytab file on one server only. Then copy the keytab file to the other servers.

2. Create a script, /usr/local/sbin/ipa-activate-all, with the following contents to activate all users:

#!/bin/bash

kinit -k -i activator

ipa stageuser-find --all --raw | grep " uid:" | cut -d ":" -f 2 | while read uid; do ipa stageuser-activate \${uid}; done

3. Edit the permissions and ownership of the **ipa-activate-all** script to make it executable:

chmod 755 /usr/local/sbin/ipa-activate-all # chown root:root /usr/local/sbin/ipa-activate-all

4. Create a systemd unit file, /etc/systemd/system/ipa-activate-all.service, with the following contents:

[Unit]

Description=Scan IdM every minute for any stage users that must be activated

[Service]

Environment=KRB5_CLIENT_KTNAME=/etc/krb5.ipa-activation.keytab Environment=KRB5CCNAME=FILE:/tmp/krb5cc_ipa-activate-all ExecStart=/usr/local/sbin/ipa-activate-all

5. Create a systemd timer, /etc/systemd/system/ipa-activate-all.timer, with the following contents:

[Unit]

Description=Scan IdM every minute for any stage users that must be activated

[Timer]

OnBootSec=15min

OnUnitActiveSec=1min

[Install]

WantedBy=multi-user.target

6. Reload the new configuration:

systemctl daemon-reload

7. Enable ipa-activate-all.timer:

systemctl enable ipa-activate-all.timer

8. Start ipa-activate-all.timer:

systemctl start ipa-activate-all.timer

9. Optional: Verify that the **ipa-activate-all.timer** daemon is running:

systemctl status ipa-activate-all.timer

ipa-activate-all.timer - Scan IdM every minute for any stage users that must be activated Loaded: loaded (/etc/systemd/system/ipa-activate-all.timer; enabled; vendor preset:

disabled)

Active: active (waiting) since Wed 2020-06-10 16:34:55 CEST; 15s ago

Trigger: Wed 2020-06-10 16:35:55 CEST; 44s left

Jun 10 16:34:55 server.idm.example.com systemd[1]: Started Scan IdM every minute for any stage users that must be activated.

11.3. ADDING AN IDM STAGE USER DEFINED IN AN LDIF FILE

Follow this procedure to access IdM LDAP and use an LDIF file to add stage users. While the example below shows adding one single user, multiple users can be added in one file in bulk mode.

Prerequisites

- IdM administrator has created the **provisionator** account and a password for it. For details, see Preparing IdM accounts for automatic activation of stage user accounts.
- You as the external administrator know the password of the **provisionator** account.
- You can SSH to the IdM server from your LDAP server.
- You are able to supply the minimal set of attributes that an IdM stage user must have to allow the correct processing of the user life cycle, namely:
 - The distinguished name (dn)
 - The **common name** (cn)
 - The **last name** (sn)
 - The **uid**

Procedure

1. On the external server, create an LDIF file that contains information about the new user:

dn: uid=stageidmuser,cn=staged

users,cn=accounts,cn=provisioning,dc=idm,dc=example,dc=com

changetype: add objectClass: top

objectClass: inetorgperson

uid: stageidmuser sn: surname

givenName: first_name

cn: full_name

2. Transfer the LDIF file from the external server to the IdM server:

\$ scp add-stageidmuser.ldif provisionator@server.idm.example.com:/provisionator/

Password:

add-stageidmuser.ldif

217.6KB/s 00:00

100% 364

3. Use the **SSH** protocol to connect to the IdM server as **provisionator**:

\$ ssh provisionator@server.idm.example.com Password:

4. On the IdM server, obtain the Kerberos ticket-granting ticket (TGT) for the provisionator account:

\$ kinit provisionator

5. Enter the **Idapadd** command with the -f option and the name of the LDIF file. Specify the name of the IdM server and the port number:

\$ Idapadd -h server.idm.example.com -p 389 -f add-stageidmuser.ldif

SASL/GSSAPI authentication started

SASL username: provisionator@IDM.EXAMPLE.COM

SASL SSF: 256

SASL data security layer installed.

adding the entry "uid=stageidmuser,cn=staged

users,cn=accounts,cn=provisioning,dc=idm,dc=example,dc=com"

11.4. ADDING AN IDM STAGE USER DIRECTLY FROM THE CLI USING LDAPMODIFY

Follow this procedure to access access Identity Management (IdM) LDAP and use the **Idapmodify** utility to add a stage user.

Prerequisites

- The IdM administrator has created the **provisionator** account and a password for it. For details, see Preparing IdM accounts for automatic activation of stage user accounts .
- You as the external administrator know the password of the **provisionator** account.
- You can SSH to the IdM server from your LDAP server.
- You are able to supply the minimal set of attributes that an IdM stage user must have to allow the correct processing of the user life cycle, namely:
 - The distinguished name (dn)
 - The common name (cn)
 - The **last name** (sn)
 - The uid

Procedure

1. Use the **SSH** protocol to connect to the IdM server using your IdM identity and credentials:

\$ ssh provisionator@server.idm.example.com Password:

2. Obtain the TGT of the **provisionator** account, an IdM user with a role to add new stage users:

\$ kinit provisionator

3. Enter the **Idapmodify** command and specify Generic Security Services API (GSSAPI) as the Simple Authentication and Security Layer (SASL) mechanism to use for authentication. Specify the name of the IdM server and the port:

Idapmodify -h server.idm.example.com -p 389 -Y GSSAPI

SASL/GSSAPI authentication started

SASL username: provisionator@IDM.EXAMPLE.COM

SASL SSF: 56

SASL data security layer installed.

4. Enter the **dn** of the user you are adding:

dn: uid=stageuser,cn=staged users,cn=accounts,cn=provisioning,dc=idm,dc=example,dc=com

5. Enter **add** as the type of change you are performing:

changetype: add

6. Specify the LDAP object class categories required to allow the correct processing of the user life cycle:

objectClass: top

objectClass: inetorgperson

You can specify additional object classes.

7. Enter the **uid** of the user:

uid: stageuser

8. Enter the cn of the user:

cn: Babs Jensen

9. Enter the last name of the user:

sn: Jensen

10. Press **Enter** again to confirm that this is the end of the entry:

[Enter]

adding new entry "uid=stageuser,cn=staged users,cn=accounts,cn=provisioning,dc=idm,dc=example,dc=com"

11. Exit the connection using **Ctrl** + **C**.

Verification

Verify the contents of the stage entry to make sure your provisioning system added all required POSIX attributes and the stage entry is ready to be activated.

• To display the new stage user's LDAP attributes, enter the **ipa stageuser-show --all --raw** command:

\$ ipa stageuser-show stageuser --all --raw

dn: uid=stageuser,cn=staged

users,cn=accounts,cn=provisioning,dc=idm,dc=example,dc=com

uid: stageuser sn: Jensen cn: Babs Jensen

has_password: FALSE has_keytab: FALSE nsaccountlock: TRUE

objectClass: top

objectClass: inetorgperson

objectClass: organizationalPerson

objectClass: person

Note that the user is explicitly disabled by the **nsaccountlock** attribute.

11.5. ADDITIONAL RESOURCES

• Using Idapmodify to manage IdM users externally .

CHAPTER 12. MANAGING KERBEROS PRINCIPAL ALIASES FOR USERS, HOSTS, AND SERVICES

When you create a new user, host, or service, a Kerberos principal in the following format is automatically added:

- user_name@REALM
- host/host_name@REALM
- service_name/host_name@REALM

Administrators can enable users, hosts, or services to authenticate against Kerberos applications using an alias. This is beneficial in the following scenarios:

- The user name changed and the user wants to log in using both the previous and new user name.
- The user needs to log in using the email address even if the IdM Kerberos realm differs from the email domain.

Note that if you rename a user, the object keeps the aliases and the previous canonical principal name.

12.1. ADDING A KERBEROS PRINCIPAL ALIAS

You can associate alias names with existing Kerberos principals in an Identity Management (IdM) environment. This enhances security and simplifies authentication processes within the IdM domain.

Procedure

• To add the alias name **useralias** to the account **user**, enter:

```
# ipa user-add-principal <user> <useralias>
------
Added new aliases to user "user"
------
User login: user
Principal alias: user@IDM.EXAMPLE.COM, useralias@IDM.EXAMPLE.COM
```

To add an alias to a host or service, use the **ipa host-add-principal** or **ipa service-add-principal** command respectively instead.

If you use an alias name to authenticate, use the -C option with the kinit command:

kinit -C <useralias>
Password for <user>@IDM.EXAMPLE.COM:

12.2. REMOVING A KERBEROS PRINCIPAL ALIAS

You can remove alias names associated with Kerberos principals in their Identity Management (IdM) environment.

Procedure

To remove the alias useralias from the account user, enter:

ipa user-remove-principal <user> <useralias> -----Removed aliases from user "user" -----User login: user Principal alias: user@IDM.EXAMPLE.COM

To remove an alias from a host or service, use the **ipa host-remove-principal** or **ipa service-remove-principal** command respectively instead.

Note that you cannot remove the canonical principal name:

```
# ipa user-show <user>
  User login: user
...
Principal name: user@IDM.EXAMPLE.COM
```

ipa user-remove-principal user user

ipa: ERROR: invalid 'krbprincipalname': at least one value equal to the canonical principal name must be present

12.3. ADDING A KERBEROS ENTERPRISE PRINCIPAL ALIAS

You can associate enterprise principal alias names with existing Kerberos enterprise principals in an Identity Management (IdM) environment. Enterprise principal aliases can use any domain suffix except for user principal name (UPN) suffixes, NetBIOS names, or domain names of trusted Active Directory forest domains.

Procedure

• To add the enterprise principal alias **user@example.com** to the **user** account:

```
# ipa user-add-principal <user> <user\\@example.com>
------
Added new aliases to user "user"
-------
User login: user
Principal alias: user@IDM.EXAMPLE.COM, user\@example.com@IDM.EXAMPLE.COM
```

To add an enterprise alias to a host or service, use the **ipa host-add-principal** or **ipa service-add-principal** command respectively instead.

NOTE

When adding or removing enterprise principal aliases, escape the @ symbol using two backslashes (\\). Otherwise, the shell interprets the @ symbol as part of the Kerberos realm name and leads to the following error:

ipa: ERROR: The realm for the principal does not match the realm for this IPA server.

If you use an enterprise principal name to authenticate, use the **-E** option with the **kinit** command:

kinit -E <user@example.com>

Password for user\@example.com@IDM.EXAMPLE.COM:

12.4. REMOVING A KERBEROS ENTERPRISE PRINCIPAL ALIAS

You can remove enterprise principal alias names associated with Kerberos enterprise principals in their Identity Management (IdM) environment.

Procedure

• To remove the enterprise principal alias **user@example.com** from the account **user**, enter:

ipa user-remove-principal <user> <user\\@example.com>

Removed aliases from user "user"

.____

User login: user

Principal alias: user@IDM.EXAMPLE.COM

To remove an alias from a host or service, use the **ipa host-remove-principal** or **ipa service-remove-principal** command respectively instead.

NOTE

When adding or removing enterprise principal aliases, escape the @ symbol using two backslashes (\\). Otherwise, the shell interprets the @ symbol as part of the Kerberos realm name and leads to the following error:

ipa: ERROR: The realm for the principal does not match the realm for this IPA server

CHAPTER 13. STRENGTHENING KERBEROS SECURITY WITH PAC INFORMATION

You can use Identity Management (IdM) with Privilege Attribute Certificate (PAC) information by default since RHEL 8.5. You can also enable Security Identifiers (SIDs) in IdM deployments that were installed before RHEL 8.5.

13.1. PRIVILEGE ATTRIBUTE CERTIFICATE (PAC) USE IN IDM

To increase security, RHEL Identity Management (IdM) now issues Kerberos tickets with Privilege Attribute Certificate (PAC) information by default in new deployments. A PAC has rich information about a Kerberos principal, including its Security Identifier (SID), group memberships, and home directory information.

SIDs, which Microsoft Active Directory (AD) uses by default, are globally unique identifiers that are never reused. SIDs express multiple namespaces: each domain has a SID, which is a prefix in the SID of each object.

Starting from RHEL 8.5, when you install an IdM server or replica, the installation script generates SIDs for users and groups by default. This allows IdM to work with PAC data. If you installed IdM before RHEL 8.5, and you have not configured a trust with an AD domain, you may not have generated SIDs for your IdM objects. For more information about generating SIDs for your IdM objects, see Enabling Security Identifiers (SIDs) in IdM.

By evaluating PAC information in Kerberos tickets, you can control resource access with much greater detail. For example, the Administrator account in one domain has a uniquely different SID than the Administrator account in any other domain. In an IdM environment with a trust to an AD domain, you can set access controls based on globally unique SIDs rather than simple user names or UIDs that might repeat in different locations, such as every Linux **root** account having a UID of O.

13.2. ENABLING SECURITY IDENTIFIERS (SIDS) IN IDM

If you installed IdM before RHEL 8.5, and you have not configured a trust with an AD domain, you might not have generated Security Identifiers (SIDs) for your IdM objects. This is because, before, the only way to generate SIDs was to run the **ipa-adtrust-install** command to add the **Trust Controller** role to an IdM server.

As of RHEL 8.6, Kerberos in IdM requires that your IdM objects have SIDs, which are necessary for security based on Privilege Access Certificate (PAC) information.

Prerequisites

- You installed IdM before RHEL 8.5.
- You have not run the ipa-sidgen task, which is part of configuring a trust with an Active Directory domain.
- You can authenticate as the IdM admin account.

Procedure

• Enable SID usage and trigger the **SIDgen** task to generate SIDs for existing users and groups. This task might be resource-intensive:

[root@server ~]# ipa config-mod --enable-sid --add-sids

Verification

• Verify that the IdM **admin** user account entry has an **ipantsecurityidentifier** attribute with a SID that ends with **-500**, the SID reserved for the domain administrator:

[root@server ~]# ipa user-show admin --all | grep ipantsecurityidentifier ipantsecurityidentifier: S-1-5-21-2633809701-976279387-419745629-500

Additional resources

- Privilege Attribute Certificate (PAC) use in IdM
- How to solve users unable to authenticate to IPA/IDM with PAC issues -S4U2PROXY_EVIDENCE_TKT_WITHOUT_PAC error (Red Hat Knowledgebase)
- Trust controllers and trust agents
- Integrate SID configuration into base IPA installers

CHAPTER 14. MANAGING KERBEROS TICKET POLICIES

Kerberos ticket policies in Identity Management (IdM) set restrictions on Kerberos ticket access, duration, and renewal. You can configure Kerberos ticket policies for the Key Distribution Center (KDC) running on your IdM server.

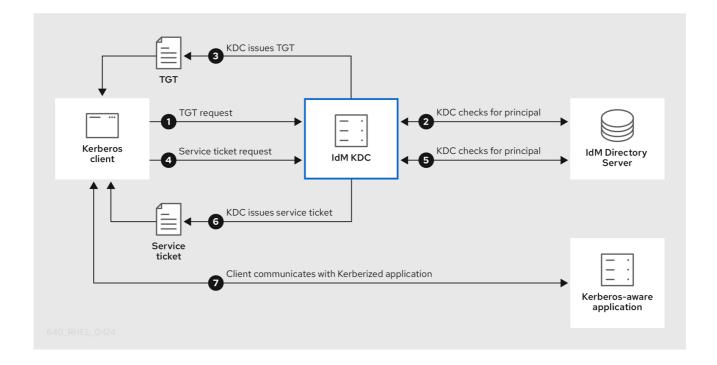

14.1. THE ROLE OF THE IDM KDC

Identity Management's authentication mechanisms use the Kerberos infrastructure established by the Key Distribution Center (KDC). The KDC is the trusted authority that stores credential information and ensures the authenticity of data originating from entities within the IdM network.

Each IdM user, service, and host acts as a Kerberos client and is identified by a unique Kerberos principal:

- For users: identifier@REALM, such as admin@EXAMPLE.COM
- For services: service/fully-qualified-hostname@REALM, such as http/server.example.com@EXAMPLE.COM
- For hosts: host/fully-qualified-hostname@REALM, such as host/client.example.com@EXAMPLE.COM

The following image is a simplification of the communication between a Kerberos client, the KDC, and a Kerberized application that the client wants to communicate with.

- 1. A Kerberos client identifies itself to the KDC by authenticating as a Kerberos principal. For example, an IdM user performs **kinit** *username* and provides their password.
- 2. The KDC checks for the principal in its database, authenticates the client, and evaluates Kerberos ticket policies to determine whether to grant the request.
- 3. The KDC issues the client a ticket-granting ticket (TGT) with a lifecycle and authentication indicators according to the appropriate ticket policy.

- 4. With the TGT, the client requests a *service ticket* from the KDC to communicate with a Kerberized service on a target host.
- 5. The KDC checks if the client's TGT is still valid, and evaluates the service ticket request against ticket policies.
- 6. The KDC issues the client a service ticket.
- 7. With the service ticket, the client can initiate encrypted communication with the service on the target host.

14.2. IDM KERBEROS TICKET POLICY TYPES

IdM Kerberos ticket policies implement the following ticket policy types:

Connection policy

To protect Kerberized services with different levels of security, you can define connection policies to enforce rules based on which pre-authentication mechanism a client used to retrieve a ticket-granting ticket (TGT).

For example, you can require smart card authentication to connect to **client1.example.com**, and require two-factor authentication to access the **testservice** application on **client2.example.com**.

To enforce connection policies, associate *authentication indicators* with services. Only clients that have the required authentication indicators in their service ticket requests are able to access those services. For more information, see Kerberos authentication indicators.

Ticket lifecycle policy

Each Kerberos ticket has a *lifetime* and a potential *renewal age*: you can renew a ticket before it reaches its maximum lifetime, but not after it exceeds its maximum renewal age.

The default global ticket lifetime is one day (86400 seconds) and the default global maximum renewal age is one week (604800 seconds). To adjust these global values, see Configuring the global ticket lifecycle policy.

You can also define your own ticket lifecycle policies:

- To configure different global ticket lifecycle values for each authentication indicator, see Configuring global ticket policies per authentication indicator.
- To define ticket lifecycle values for a single user that apply regardless of the authentication method used, see Configuring the default ticket policy for a user.
- To define individual ticket lifecycle values for each authentication indicator that only apply to a single user, see Configuring individual authentication indicator ticket policies for a user.

14.3. KERBEROS AUTHENTICATION INDICATORS

The Kerberos Key Distribution Center (KDC) attaches *authentication indicators* to a ticket-granting ticket (TGT) based on which pre-authentication mechanism the client used to prove its identity:

otp

two-factor authentication (password + One-Time Password)

radius

RADIUS authentication (commonly for 802.1x authentication)

pkinit

PKINIT, smart card, or certificate authentication

hardened

hardened passwords (SPAKE or FAST)^[1]

The KDC then attaches the authentication indicators from the TGT to any service ticket requests that stem from it. The KDC enforces policies such as service access control, maximum ticket lifetime, and maximum renewable age based on the authentication indicators.

Authentication indicators and IdM services

If you associate a service or a host with an authentication indicator, only clients that used the corresponding authentication mechanism to obtain a TGT will be able to access it. The KDC, not the application or service, checks for authentication indicators in service ticket requests, and grants or denies requests based on Kerberos connection policies.

If a service or a host has no authentication indicators assigned to it, it will accept tickets authenticated by any mechanism.

Additional resources

- Enforcing authentication indicators for an IdM service
- Enabling GSSAPI authentication and enforcing Kerberos authentication indicators for sudo on an IdM client

14.4. ENFORCING AUTHENTICATION INDICATORS FOR AN IDM SERVICE

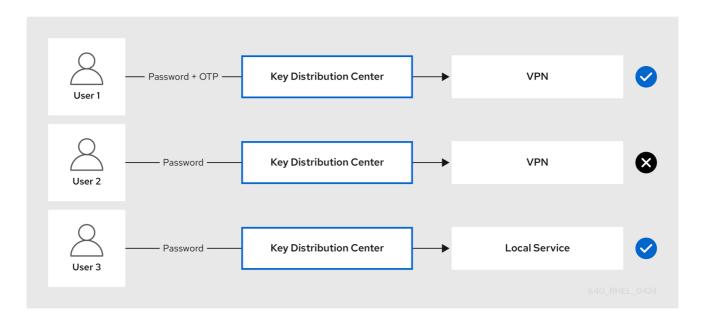

The authentication mechanisms supported by Identity Management (IdM) vary in their authentication strength. For example, obtaining the initial Kerberos ticket-granting ticket (TGT) using a one-time password (OTP) in combination with a standard password is considered more secure than authentication using only a standard password.

By associating authentication indicators with a particular IdM service, you can, as an IdM administrator, configure the service so that only users who used those specific pre-authentication mechanisms to obtain their initial ticket-granting ticket (TGT) will be able to access the service.

In this way, you can configure different IdM services so that:

- Only users who used a stronger authentication method to obtain their initial TGT, such as a one-time password (OTP), can access services critical to security, such as a VPN.
- Users who used simpler authentication methods to obtain their initial TGT, such as a password, can only access non-critical services, such as local logins.

Figure 14.1. Example of authenticating using different technologies

This procedure describes creating an IdM service and configuring it to require particular Kerberos authentication indicators from incoming service ticket requests.

14.4.1. Creating an IdM service entry and its Kerberos keytab

Adding an *IdM* service entry to IdM for a service running on an IdM host creates a corresponding Kerberos principal, and allows the service to request an SSL certificate, a Kerberos keytab, or both.

The following procedure describes creating an IdM service entry and generating an associated Kerberos keytab for encrypting communication with that service.

Prerequisites

• Your service can store a Kerberos principal, an SSL certificate, or both.

Procedure

 Add an IdM service with the ipa service-add command to create a Kerberos principal associated with it. For example, to create the IdM service entry for the testservice application that runs on host client.example.com:

[root@client ~]# ipa service-add testservice/client.example.com

Modified service "testservice/client.example.com@EXAMPLE.COM"

Principal name: testservice/client.example.com@EXAMPLE.COM

Principal alias: testservice/client.example.com@EXAMPLE.COM

Managed by: client.example.com

2. Generate and store a Kerberos keytab for the service on the client.

[root@client ~]# ipa-getkeytab -k /etc/testservice.keytab -p testservice/client.example.com
Keytab successfully retrieved and stored in: /etc/testservice.keytab

Verification

1. Display information about an IdM service with the **ipa service-show** command.

[root@server ~]# ipa service-show testservice/client.example.com

Principal name: testservice/client.example.com@EXAMPLE.COM Principal alias: testservice/client.example.com@EXAMPLE.COM

Keytab: True

Managed by: client.example.com

2. Display the contents of the service's Kerberos keytab with the **klist** command.

[root@server etc]# klist -ekt /etc/testservice.keytab

Keytab name: FILE:/etc/testservice.keytab

KVNO Timestamp Principal

---- 2 04/01/2020 17:52:55 testservice/client.example.com@EXAMPLE.COM (aes256-cts-

hmac-sha1-96)

2 04/01/2020 17:52:55 testservice/client.example.com@EXAMPLE.COM (aes128-cts-

hmac-sha1-96)

2 04/01/2020 17:52:55 testservice/client.example.com@EXAMPLE.COM (camellia128-cts-

cmac)

2 04/01/2020 17:52:55 testservice/client.example.com@EXAMPLE.COM (camellia256-cts-cmac)

14.4.2. Associating authentication indicators with an IdM service using IdM CLI

As an Identity Management (IdM) administrator, you can configure a host or a service to require that a service ticket presented by the client application contains a specific authentication indicator. For example, you can ensure that only users who used a valid IdM two-factor authentication token with their password when obtaining a Kerberos ticket-granting ticket (TGT) will be able to access that host or service.

Follow this procedure to configure a service to require particular Kerberos authentication indicators from incoming service ticket requests.

Prerequisites

- You have created an IdM service entry for a service that runs on an IdM host. See Creating an IdM service entry and its Kerberos keytab.
- You have obtained the ticket-granting ticket of an administrative user in IdM.

WARNING

Do **not** assign authentication indicators to internal IdM services. The following IdM services cannot perform the interactive authentication steps required by PKINIT and multi-factor authentication methods:

host/server.example.com@EXAMPLE.COM HTTP/server.example.com@EXAMPLE.COM Idap/server.example.com@EXAMPLE.COM DNS/server.example.com@EXAMPLE.COM cifs/server.example.com@EXAMPLE.COM

Procedure

• Use the **ipa service-mod** command to specify one or more required authentication indicators for a service, identified with the **--auth-ind** argument.

Authentication method	auth-ind value
Two-factor authentication	otp
RADIUS authentication	radius
PKINIT, smart card, or certificate authentication	pkinit
Hardened passwords (SPAKE or FAST)	hardened

For example, to require that a user was authenticated with smart card or OTP authentication to retrieve a service ticket for the **testservice** principal on host **client.example.com**:

[root@server ~]# ipa service-mod testservice/client.example.com@EXAMPLE.COM - auth-ind otpauth-ind pkinit		
Modified service "testservice/client.example.com@EXAMPLE.COM"		
Principal name: testservice/client.example.com@EXAMPLE.COM Principal alias: testservice/client.example.com@EXAMPLE.COM Authentication Indicators: otp, pkinit Managed by: client.example.com		

• To remove all authentication indicators from a service, provide an empty list of indicators:

[root@server ~]# ipa service-mod testservice/client.example.com@EXAMI auth-ind "	PLE.COM
Modified service "testservice/client.example.com@EXAMPLE.COM"	

Principal name: testservice/client.example.com@EXAMPLE.COM Principal alias: testservice/client.example.com@EXAMPLE.COM

Managed by: client.example.com

Verification

• Display information about an IdM service, including the authentication indicators it requires, with the **ipa service-show** command.

[root@server ~]# ipa service-show testservice/client.example.com Principal name: testservice/client.example.com@EXAMPLE.COM Principal alias: testservice/client.example.com@EXAMPLE.COM

Authentication Indicators: otp, pkinit

Keytab: True

Managed by: client.example.com

Additional resources

- Retrieving a Kerberos service ticket for an IdM service
- Enabling GSSAPI authentication and enforcing Kerberos authentication indicators for sudo on an IdM client

14.4.3. Associating authentication indicators with an IdM service using IdM Web UI

As an Identity Management (IdM) administrator, you can configure a host or a service to require a service ticket presented by the client application to contain a specific authentication indicator. For example, you can ensure that only users who used a valid IdM two-factor authentication token with their password when obtaining a Kerberos ticket-granting ticket (TGT) will be able to access that host or service.

Follow this procedure to use the IdM Web UI to configure a host or service to require particular Kerberos authentication indicators from incoming ticket requests.

Prerequisites

• You have logged in to the IdM Web UI as an administrative user.

Procedure

- 1. Select **Identity** → **Hosts** or **Identity** → **Services**.
- 2. Click the name of the required host or service.
- 3. Under Authentication indicators, select the required authentication method.
 - For example, selecting **OTP** ensures that only users who used a valid IdM two-factor authentication token with their password when obtaining a Kerberos TGT will be able to access the host or service.
 - If you select both **OTP** and **RADIUS**, then both users that used a valid IdM two-factor authentication token with their password when obtaining a Kerberos TGT **and** users that used the RADIUS server for obtaining their Kerberos TGT will be allowed access.
- 4. Click **Save** at the top of the page.

Additional resources

- Retrieving a Kerberos service ticket for an IdM service
- Enabling GSSAPI authentication and enforcing Kerberos authentication indicators for sudo on an IdM client

14.4.4. Retrieving a Kerberos service ticket for an IdM service

The following procedure describes retrieving a Kerberos service ticket for an IdM service. You can use this procedure to test Kerberos ticket policies, such as enforcing that certain Kerberos authentication indicators are present in a ticket-granting ticket (TGT).

Prerequisites

- If the service you are working with is not an internal IdM service, you have created a corresponding *IdM* service entry for it. See Creating an IdM service entry and its Kerberos keytab.
- You have a Kerberos ticket-granting ticket (TGT).

Procedure

• Use the **kvno** command with the **-S** option to retrieve a service ticket, and specify the name of the IdM service and the fully-qualified domain name of the host that manages it.

[root@server ~]# kvno -S testservice client.example.com testservice/client.example.com@EXAMPLE.COM: kvno = 1

NOTE

If you need to access an IdM service and your current ticket-granting ticket (TGT) does not possess the required Kerberos authentication indicators associated with it, clear your current Kerberos credentials cache with the **kdestroy** command and retrieve a new TGT:

[root@server ~]# kdestroy

For example, if you initially retrieved a TGT by authenticating with a password, and you need to access an IdM service that has the **pkinit** authentication indicator associated with it, destroy your current credentials cache and re-authenticate with a smart card. See Kerberos authentication indicators.

Verification

• Use the **klist** command to verify that the service ticket is in the default Kerberos credentials cache.

[root@server etc]# **klist_** Ticket cache: KCM:1000

Default principal: admin@EXAMPLE.COM

Valid starting Expires Service principal

04/01/2020 12:52:42 04/02/2020 12:52:39 krbtgt/EXAMPLE.COM@EXAMPLE.COM 04/01/2020 12:54:07 04/02/2020 12:52:39 testservice/client.example.com@EXAMPLE.COM

14.4.5. Additional resources

• Kerberos authentication indicators.

14.5. CONFIGURING THE GLOBAL TICKET LIFECYCLE POLICY

The global ticket policy applies to all service tickets and to users that do not have any per-user ticket policies defined.

The following procedure describes adjusting the maximum ticket lifetime and maximum ticket renewal age for the global Kerberos ticket policy using the **ipa krbtpolicy-mod** command.

While using the **ipa krbtpolicy-mod** command, specify at least one of the following arguments:

- --maxlife for the maximum ticket lifetime in seconds
- --maxrenew for the maximum renewable age in seconds

Procedure

1. To modify the global ticket policy:

```
[root@server ~]# ipa krbtpolicy-mod --maxlife=$((8*60*60)) --maxrenew=$((24*60*60)) Max life: 28800 Max renew: 86400
```

In this example, the maximum lifetime is set to eight hours (8 * 60 minutes * 60 seconds) and the maximum renewal age is set to one day (24 * 60 minutes * 60 seconds).

2. Optional: To reset the global Kerberos ticket policy to the default installation values:

```
[root@server ~]# ipa krbtpolicy-reset
Max life: 86400
Max renew: 604800
```

Verification

Display the global ticket policy:

```
[root@server ~]# ipa krbtpolicy-show
Max life: 28800
Max renew: 86640
```

Additional resources

- Configuring the default ticket policy for a user
- Configuring individual authentication indicator ticket policies for a user

14.6. CONFIGURING GLOBAL TICKET POLICIES PER AUTHENTICATION INDICATOR

Follow this procedure to adjust the global maximum ticket lifetime and maximum renewable age for each authentication indicator. These settings apply to users that do not have per-user ticket policies defined.

Use the **ipa krbtpolicy-mod** command to specify the global maximum lifetime or maximum renewable age for Kerberos tickets depending on the authentication indicators attached to them.

Procedure

• For example, to set the global two-factor ticket lifetime and renewal age values to one week, and the global smart card ticket lifetime and renewal age values to two weeks:

[root@server ~]# ipa krbtpolicy-mod --otp-maxlife=604800 --otp-maxrenew=604800 --pkinit-maxlife=172800 --pkinit-maxrenew=172800

Verification

Display the global ticket policy:

[root@server ~]# ipa krbtpolicy-show

Max life: 86400

OTP max life: 604800 PKINIT max life: 172800 Max renew: 604800

OTP max renew: 604800 PKINIT max renew: 172800

Notice that the OTP and PKINIT values are different from the global default **Max life** and **Max renew** values.

Additional resources

- Authentication indicator options for the krbtpolicy-mod command
- Configuring the default ticket policy for a user
- Configuring individual authentication indicator ticket policies for a user

14.7. CONFIGURING THE DEFAULT TICKET POLICY FOR A USER

You can define a unique Kerberos ticket policy that only applies to a single user. These per-user settings override the global ticket policy, for all authentication indicators.

Use the **ipa krbtpolicy-mod** username command, and specify at least one of the following arguments:

- --maxlife for the maximum ticket lifetime in seconds
- --maxrenew for the maximum renewable age in seconds

Procedure

1. For example, to set the IdM **admin** user's maximum ticket lifetime to two days and maximum renewal age to two weeks:

[root@server ~]# ipa krbtpolicy-mod admin --maxlife=172800 --maxrenew=1209600

Max life: 172800 Max renew: 1209600

2. Optional: To reset the ticket policy for a user:

[root@server ~]# ipa krbtpolicy-reset admin

Verification

• Display the effective Kerberos ticket policy that applies to a user:

[root@server ~]# ipa krbtpolicy-show admin

Max life: 172800 Max renew: 1209600

Additional resources

- Configuring the global ticket lifecycle policy
- Configuring global ticket policies per authentication indicator

14.8. CONFIGURING INDIVIDUAL AUTHENTICATION INDICATOR TICKET POLICIES FOR A USER

As an administrator, you can define Kerberos ticket policies for a user that differ per authentication indicator. For example, you can configure a policy to allow the IdM **admin** user to renew a ticket for two days if it was obtained with OTP authentication, and a week if it was obtained with smart card authentication.

These per-authentication indicator settings will override the *user's* default ticket policy, the *global* default ticket policy, and any *global* authentication indicator ticket policy.

Use the **ipa krbtpolicy-mod** *username* command to set custom maximum lifetime and maximum renewable age values for a user's Kerberos tickets depending on the authentication indicators attached to them.

Procedure

1. For example, to allow the IdM **admin** user to renew a Kerberos ticket for two days if it was obtained with One-Time Password authentication, set the **--otp-maxrenew** option:

[root@server ~]# ipa krbtpolicy-mod admin --otp-maxrenew=\$((2*24*60*60)) OTP max renew: 172800

2. Optional: To reset the ticket policy for a user:

[root@server ~]# ipa krbtpolicy-reset username

Verification

• Display the effective Kerberos ticket policy that applies to a user:

[root@server ~]# ipa krbtpolicy-show admin Max life: 28800 Max renew: 86640

Additional resources

- Authentication indicator options for the **krbtpolicy-mod** command
- Configuring the default ticket policy for a user
- Configuring the global ticket lifecycle policy
- Configuring global ticket policies per authentication indicator

14.9. AUTHENTICATION INDICATOR OPTIONS FOR THE KRBTPOLICY-MOD COMMAND

Specify values for authentication indicators with the following arguments.

Table 14.1. Authentication indicator options for the krbtpolicy-mod command

Authentication indicator	Argument for maximum lifetime	Argument for maximum renewal age
otp	otp-maxlife	otp-maxrenew
radius	radius-maxlife	radius-maxrenew
pkinit	pkinit-maxlife	pkinit-maxrenew
hardened	hardened-maxlife	hardened-maxrenew

^[1] A hardened password is protected against brute-force password dictionary attacks by using Single-Party Public-Key Authenticated Key Exchange (SPAKE) pre-authentication and/or Flexible Authentication via Secure Tunneling (FAST) armoring.

CHAPTER 15. KERBEROS PKINIT AUTHENTICATION IN IDM

Public Key Cryptography for Initial Authentication in Kerberos (PKINIT) is a preauthentication mechanism for Kerberos. The Identity Management (IdM) server includes a mechanism for Kerberos PKINIT authentication.

15.1. DEFAULT PKINIT CONFIGURATION

The default PKINIT configuration on your IdM servers depends on the certificate authority (CA) configuration.

Table 15.1. Default PKINIT configuration in IdM

CA configuration	PKINIT configuration
Without a CA, no external PKINIT certificate provided	Local PKINIT: IdM only uses PKINIT for internal purposes on servers.
Without a CA, external PKINIT certificate provided to IdM	IdM configures PKINIT by using the external Kerberos key distribution center (KDC) certificate and CA certificate.
With an Integrated CA	IdM configures PKINIT by using the certificate signed by the IdM CA.

15.2. DISPLAYING THE CURRENT PKINIT CONFIGURATION

IdM provides multiple commands you can use to query the PKINIT configuration in your domain.

Procedure

• To determine the PKINIT status in your domain, use the **ipa pkinit-status** command:

\$ ipa pkinit-status

Server name: server1.example.com

PKINIT status: **enabled** [...output truncated...]

Server name: server2.example.com

PKINIT status: **disabled** [...output truncated...]

The command displays the PKINIT configuration status as **enabled** or **disabled**:

- **enabled**: PKINIT is configured using a certificate signed by the integrated IdM CA or an external PKINIT certificate.
- **disabled**: IdM only uses PKINIT for internal purposes on IdM servers.
- To list the IdM servers with active Kerberos key distribution centers (KDCs) that support PKINIT for IdM clients, use the ipa config-show command on any server:

\$ ipa config-show

Maximum username length: 32 Home directory base: /home

Default shell: /bin/sh

Default users group: ipausers

[...output truncated...]

IPA masters capable of PKINIT: server1.example.com

[...output truncated...]

15.3. CONFIGURING PKINIT IN IDM

If your IdM servers are running with PKINIT disabled, use these steps to enable it. For example, a server is running with PKINIT disabled if you passed the **--no-pkinit** option with the **ipa-server-install** or **ipa-replica-install** utilities.

Prerequisites

 Ensure that all IdM servers with a certificate authority (CA) installed are running on the same domain level.

Procedure

1. Check if PKINIT is enabled on the server:

kinit admin Password for admin@IDM.EXAMPLE.COM: # ipa pkinit-status --server=server.idm.example.com 1 server matched -----Server name: server.idm.example.com PKINIT status:enabled -----Number of entries returned 1

If PKINIT is disabled, you will see the following output:

You can also use the command to find all the servers where PKINIT is enabled if you omit the **-- server_fqdn>** parameter.

- 2. If you are using IdM without CA:
 - a. On the IdM server, install the CA certificate that signed the Kerberos key distribution center (KDC) certificate:

ipa-cacert-manage install -t CT,C,C ca.pem

b. To update all IPA hosts, repeat the **ipa-certupdate** command on all replicas and clients:

ipa-certupdate

c. Check if the CA certificate has already been added using the **ipa-cacert-manage list** command. For example:

ipa-cacert-manage list CN=CA,O=Example Organization The ipa-cacert-manage command was successful

- d. Use the **ipa-server-certinstall** utility to install an external KDC certificate. The KDC certificate must meet the following conditions:
 - It is issued with the common name
 CN=fully_qualified_domain_name,certificate_subject_base.
 - It includes the Kerberos principal **krbtqt**/**REALM NAME@REALM NAME**.
 - It contains the Object Identifier (OID) for KDC authentication: 1.3.6.1.5.2.3.5.

ipa-server-certinstall --kdc kdc.pem kdc.key

systemctl restart krb5kdc.service

e. See your PKINIT status:

ipa pkinit-status

Server name: server1.example.com

PKINIT status: enabled [...output truncated...]

Server name: server2.example.com

PKINIT status: disabled [...output truncated...]

3. If you are using IdM with a CA certificate, enable PKINIT as follows:

ipa-pkinit-manage enable
Configuring Kerberos KDC (krb5kdc)
[1/1]: installing X509 Certificate for PKINIT
Done configuring Kerberos KDC (krb5kdc).
The ipa-pkinit-manage command was successful

If you are using an IdM CA, the command requests a PKINIT KDC certificate from the CA.

Additional resources

• ipa-server-certinstall(1) man page on your system

15.4. ADDITIONAL RESOURCES

For details on Kerberos PKINIT, PKINIT configuration in the MIT Kerberos Documentation.

CHAPTER 16. MAINTAINING IDM KERBEROS KEYTAB FILES

Learn more about what Kerberos keytab files are and how Identity Management (IdM) uses them to allow services to authenticate securely with Kerberos.

You can use this information to understand why you should protect these sensitive files, and to troubleshoot communication issues between IdM services.

16.1. HOW IDENTITY MANAGEMENT USES KERBEROS KEYTAB FILES

A Kerberos keytab is a file containing Kerberos principals and their corresponding encryption keys. Hosts, services, users, and scripts can use keytabs to authenticate to the Kerberos Key Distribution Center (KDC) securely, without requiring human interaction.

Every IdM service on an IdM server has a unique Kerberos principal stored in the Kerberos database. For example, if IdM servers **east.idm.example.com** and **west.idm.example.com** provide DNS services, IdM creates 2 unique DNS Kerberos principals to identify these services, which follow the naming convention **<service>/host.domain.com@REALM.COM**:

- DNS/east.idm.example.com@IDM.EXAMPLE.COM
- DNS/west.idm.example.com@IDM.EXAMPLE.COM

IdM creates a keytab on the server for each of these services to store a local copy of the Kerberos keys, along with their Key Version Numbers (KVNO). For example, the default keytab file /etc/krb5.keytab stores the host principal, which represents that machine in the Kerberos realm and is used for login authentication. The KDC generates encryption keys for the different encryption algorithms it supports, such as aes256-cts-hmac-sha1-96 and aes128-cts-hmac-sha1-96.

You can display the contents of a keytab file with the **klist** command:

[root@idmserver ~]# klist -ekt /etc/krb5.keytab

Keytab name: FILE:/etc/krb5.keytab KVNO Timestamp Principal

2 02/24/2022 20:28:09 host/idmserver.idm.example.com@IDM.EXAMPLE.COM (aes256-cts-hmacsha1-96)

2 02/24/2022 20:28:09 host/idmserver.idm.example.com@IDM.EXAMPLE.COM (aes128-cts-hmacsha1-96)

2 02/24/2022 20:28:09 host/idmserver.idm.example.com@IDM.EXAMPLE.COM (camellia128-cts-cmac)

2 02/24/2022 20:28:09 host/idmserver.idm.example.com@IDM.EXAMPLE.COM (camellia256-cts-cmac)

Additional resources

- Verifying that Kerberos keytab files are in sync with the IdM database
- List of IdM Kerberos keytab files and their contents

16.2. VERIFYING THAT KERBEROS KEYTAB FILES ARE IN SYNC WITH THE IDM DATABASE

When you change a Kerberos password, IdM automatically generates a new corresponding Kerberos key

and increments its Key Version Number (KVNO). If a Kerberos keytab is not updated with the new key and KVNO, any services that depend on that keytab to retrieve a valid key might not be able to authenticate to the Kerberos Key Distribution Center (KDC).

If one of your IdM services cannot communicate with another service, use the following procedure to verify that your Kerberos keytab files are in sync with the keys stored in the IdM database. If they are out of sync, retrieve a Kerberos keytab with an updated key and KVNO. This example compares and retrieves an updated **DNS** principal for an IdM server.

Prerequisites

- You must authenticate as the IdM admin account to retrieve keytab files
- You must authenticate as the **root** account to modify keytab files owned by other users

Procedure

 Display the KVNO of the principals in the keytab you are verifying. In the following example, the /etc/named.keytab file has the key for the DNS/server1.idm.example.com@EXAMPLE.COM principal with a KVNO of 2.

[root@server1 ~]# klist -ekt /etc/named.keytab Keytab name: FILE:/etc/named.keytab KVNO Timestamp Principal

2 11/26/2021 13:51:11 DNS/server1.idm.example.com@EXAMPLE.COM (aes256-cts-hmac-sha1-96)

2 11/26/2021 13:51:11 DNS/server1.idm.example.com@EXAMPLE.COM (aes128-cts-hmac-sha1-96)

2 11/26/2021 13:51:11 DNS/server1.idm.example.com@EXAMPLE.COM (camellia128-cts-cmac)

2 11/26/2021 13:51:11 DNS/server1.idm.example.com@EXAMPLE.COM (camellia256-cts-cmac)

2. Display the KVNO of the principal stored in the IdM database. In this example, the KVNO of the key in the IdM database does not match the KVNO in the keytab.

[root@server1 ~]# kvno DNS/server1.idm.example.com@EXAMPLE.COM DNS/server1.idm.example.com@EXAMPLE.COM: kvno = 3

3. Authenticate as the IdM admin account.

[root@server1 ~]# kinit admin Password for admin@IDM.EXAMPLE.COM:

4. Retrieve an updated Kerberos key for the principal and store it in its keytab. Perform this step as the **root** user so you can modify the /**etc/named.keytab** file, which is owned by the **named** user.

[root@server1 ~]# ipa-getkeytab -s server1.idm.example.com -p DNS/server1.idm.example.com -k /etc/named.keytab

Verification

1. Display the updated KVNO of the principal in the keytab.

[root@server1 ~]# klist -ekt /etc/named.keytab

Keytab name: FILE:/etc/named.keytab KVNO Timestamp Principal

4 08/17/2022 14:42:11 DNS/server1.idm.example.com@EXAMPLE.COM (aes256-cts-hmac-sha1-96)

4 08/17/2022 14:42:11 DNS/server1.idm.example.com@EXAMPLE.COM (aes128-cts-hmac-sha1-96)

4 08/17/2022 14:42:11 DNS/server1.idm.example.com@EXAMPLE.COM (camellia128-cts-cmac)

4 08/17/2022 14:42:11 DNS/server1.idm.example.com@EXAMPLE.COM (camellia256-cts-cmac)

2. Display the KVNO of the principal stored in the IdM database and ensure it matches the KVNO from the keytab.

[root@server1 ~]# kvno DNS/server1.idm.example.com@EXAMPLE.COM DNS/server1.idm.example.com@EXAMPLE.COM: kvno = 4

Additional resources

- How Identity Management uses Kerberos keytab files
- List of IdM Kerberos keytab files and their contents

16.3. LIST OF IDM KERBEROS KEYTAB FILES AND THEIR CONTENTS

The following table displays the location, contents, and purpose of the IdM Kerberos keytab files.

Table 16.1. Table

Keytab location	Contents	Purpose
/etc/krb5.keytab	host principal	Verifying user credentials when logging in, used by NFS if there is no nfs principal
/etc/dirsrv/ds.keytab	Idap principal	Authenticating users to the IdM database, securely replicating database contents between IdM replicas
/var/lib/ipa/gssproxy/http.key tab	HTTP principal	Authenticating to the Apache server
/etc/named.keytab	DNS principal	Securely updating DNS records
/etc/ipa/dnssec/ipa- dnskeysyncd.keytab	ipa-dnskeysyncd principal	Keeping OpenDNSSEC synchronized with LDAP

Keytab location	Contents	Purpose
/etc/pki/pki- tomcat/dogtag.keytab	dogtag principal	Communicating with the Certificate Authority (CA)
/etc/samba/samba.keytab	cifs and host principals	Communicating with the Samba service
/var/lib/sss/keytabs/ <i>ad-domain.com</i> .keytab	Active Directory (AD) domain controller (DCs) principals in the form HOSTNAME\$@AD- DOMAIN.COM	Communicating with AD DCs through an IdM-AD Trust

Additional resources

- How Identity Management uses Kerberos keytab files
- Verifying that Kerberos keytab files are in sync with the IdM database

16.4. VIEWING THE ENCRYPTION TYPE OF YOUR IDM MASTER KEY

As an Identity Management (IdM) administrator, you can view the encryption type of your IdM master key, which is the key that the IdM Kerberos Distribution Center (KDC) uses to encrypt all other principals when storing them at rest. Knowing the encryption type helps you determine your deployment's compatibility with FIPS standards.

As of RHEL 8.7, the encryption type is **aes256-cts-hmac-sha384-192**. This encryption type is compatible with the default RHEL 9 FIPS cryptographic policy aiming to comply with FIPS 140-3.

The encryption types used on previous RHEL versions are not compatible with RHEL 9 systems that adhere to FIPS 140–3 standards. To make RHEL 9 systems compatible with a RHEL 8 FIPS 140–2 deployment, see the AD Domain Users unable to login in to the FIPS-compliant environment KCS solution.

Prerequisites

• You have **root** access to any of the RHEL 8 replicas in the IdM deployment.

Procedure

• On the replica, view the encryption type on the command line:

kadmin.local getprinc K/M | grep -E '^Key:' Key: vno 1, aes256-cts-hmac-sha1-96

The **aes256-cts-hmac-sha1-96** key in the output indicates that the IdM deployment was installed on a server that was running RHEL 8.6 or earlier. The presence of a **aes256-cts-hmac-sha384-192** key in the output would indicate that the IdM deployment was installed on a server that was running RHEL 8.7 or later.

CHAPTER 17. ENABLING PASSKEY AUTHENTICATION IN IDM ENVIRONMENT

The Fast IDentity Online 2 (FIDO2) standard is based on public key cryptography and adds the option of a passwordless flow with PIN or biometrics. The passkey authentication in the IdM environment uses FIDO2 compatible devices supported by the **libfido2** library.

The passkey authentication method provides an additional security layer to comply with regulatory standards by including passwordless and multi-factor authentication (MFA) that require a PIN or a fingerprint. It uses a combination of special hardware and software, such as passkey device and passkey enablement in an Identity Management (IdM) environment, to strengthen the security in the environment where data protection plays a key role.

If your system is connected to a network with the IdM environment, the passkey authentication method issues a Kerberos ticket automatically, which enables single sign-on (SSO) for an IdM user.

You can use passkey to authenticate through the graphical interface to your operating system. If your system allows you to authenticate with passkey and password, you can skip passkey authentication and authenticate with the password by pressing **Space** on your keyboard followed by the **Enter** key. If you use GNOME Desktop Manager (GDM), you can press **Enter** to bypass the passkey authentication.

Note that, currently, the passkey authentication in the IdM environment does not support FIDO2 attestation mechanism, which allows for the identification of the particular passkey device.

The following procedures provide instructions on managing and configuring passkey authentication in an IdM environment.

17.1. PREREQUISITES

- You have a passkey device.
- Install the fido2-tools package:
 - # dnf install fido2-tools
- Set the PIN for the passkey device:
 - 1. Connect the passkey device to the USB port.
 - 2. List the connected passkey devices:
 - # fido2-token -L
 - 3. Set the PIN for your passkey device by following the command prompts.
 - # fido2-token -C passkey_device
- You have installed the **sssd-passkey** package.

17.2. REGISTERING A PASSKEY DEVICE

As a user you can configure authentication with a passkey device. A passkey device is compatible with any FIDO2 specification device, such as YubiKey 5 NFC. To configure this authentication method, follow the instructions below.

Prerequisites

- The PIN for the passkey device is set.
- Passkey authentication is enabled for an IdM user:

ipa user-add user01 --first=user --last=01 --user-auth-type=passkey

Use the **ipa user-mod** with the same **--user-auth-type=passkey** parameter for an existing IdM user.

• Access to the physical machine to which the user wants to authenticate.

Procedure

- 1. Insert the passkey device in the USB port.
- 2. Register the passkey for the IdM user:

ipa user-add-passkey user01 --register

Follow the application prompts:

- a. Enter the PIN for the passkey device.
- b. Touch the device to verify your identity. If you are using a biometric device, ensure to use the same finger with which you registered the device.

It is good practice for users to configure multiple passkey devices as a backup that allows authentication from multiple locations or devices. To ensure the Kerberos ticket is issued during authentication, do not configure more than 12 passkey devices for a user.

Verification

- 1. Log in to the system with the username you have configured to use passkey authentication. The system prompts you to insert the passkey device:
 - Insert your passkey device, then press ENTER.
- 2. Insert the passkey device into the USB port and enter your PIN when prompted:

Enter PIN: Creating home directory for *user01@example.com*.

3. Confirm the Kerberos ticket is issued:

\$ klist

Default principal: user01@IPA.EXAMPLE.COM

Note, to skip passkey authentication, enter any character in the prompt or enter an empty PIN if user authentication is enabled. The system redirects you to password based authentication.

NOTE

If you enter the PIN for your passkey device incorrectly 3 times, disconnect the physical token and reconnect it to the USB port and perform a successful authentication. If you do not complete a power cycle, you will not be able to authenticate even if you enter the PIN correctly.

17.3. AUTHENTICATION POLICIES

Use authentication policies to configure the available online and local authentication methods.

Authentication with online connection

Uses all online authentication methods that the service provides on the server side. For IdM, AD, or Kerberos services, the default authentication method is Kerberos.

Authentication without online connection

Uses authentication methods that are available for a user. You can tune the authentication method with the **local_auth_policy** option.

Use the **local_auth_policy** option in the **/etc/sssd/sssd.conf** file to configure the available online and offline authentication methods. By default, the authentication is performed only with the methods that the server side of the service supports. You can tune the policy with the following values:

- The match value enables the matching of offline and online states. For example, the IdM server supports online passkey authentication and match enables offline and online authentications for the passkey method.
- The **only** value offers only offline methods and ignores the online methods.
- The **enable** and **disable** values explicitly define the methods for offline authentication. For example, **enable:passkey** enables only passkey for offline authentication.

The following configuration example allows local users to authenticate locally using smart card authentication:

[domain/shadowutils]
id_provider = proxy
proxy_lib_name = files
auth_provider = none
local_auth_policy = only

The **local_auth_policy** option applies to the passkey and smart card authentication methods.

17.4. RETRIEVING AN IDM TICKET-GRANTING TICKET AS A PASSKEY USER

To retrieve a Kerberos ticket-granting ticket (TGT) as a passkey user, request an anonymous Kerberos ticket and enable Flexible Authentication via Secure Tunneling (FAST) channel to provide a secure connection between the Kerberos client and Kerberos Distribution Center (KDC).

Prerequisites

- Your IdM client and IdM servers use RHEL 9.1 or later.
- Your IdM client and IdM servers use SSSD 2.7.0 or later.
- You registered your passkey device and configured your authentication policies.

Procedure

1. Initialize the credentials cache by running the following command:

[root@client ~]# kinit -n @IDM.EXAMPLE.COM -c FILE:armor.ccache

Note that this command creates the armor.ccache file that you need to point to whenever you request a new Kerberos ticket.

2. Request a Kerberos ticket by running the command:

[root@client ~]# kinit -T FILE:armor.ccache <username>@IDM.EXAMPLE.COM Enter your PIN:

NOTE

If you enter the PIN for your passkey device incorrectly 3 times, disconnect the physical token and reconnect it to the USB port and perform a successful authentication. If you do not complete a power cycle, you will not be able to authenticate even if you enter the PIN correctly.

Verification

Display your Kerberos ticket information:

[root@client ~]# klist -C Ticket cache: KCM:0:58420

Default principal: <username>@IDM.EXAMPLE.COM

Valid starting Expires Service principal

05/09/22 07:48:23 05/10/22 07:03:07 krbtgt/IDM.EXAMPLE.COM@IDM.EXAMPLE.COM

config: fast_avail(krbtgt/IDM.EXAMPLE.COM@IDM.EXAMPLE.COM) = yes

08/17/2022 20:22:45 08/18/2022 20:22:43

krbtgt/IDM.EXAMPLE.COM@IDM.EXAMPLE.COM

config: pa_type(krbtgt/IDM.EXAMPLE.COM@IDM.EXAMPLE.COM) = 153

The **pa_type = 153** indicates passkey authentication.

CHAPTER 18. USING THE KDC PROXY IN IDM

Some administrators might choose to make the default Kerberos ports inaccessible in their deployment. To allow users, hosts, and services to obtain Kerberos credentials, you can use the **HTTPS** service as a proxy that communicates with Kerberos via the **HTTPS** port 443.

In Identity Management (IdM), the **Kerberos Key Distribution Center Proxy**(KKDCP) provides this functionality.

On an IdM server, KKDCP is enabled by default and available at https://cserver.idm.example.com/KdcProxy. On an IdM client, you must change its Kerberos configuration to access the KKDCP.

18.1. CONFIGURING AN IDM CLIENT TO USE KKDCP

As an Identity Management (IdM) system administrator, you can configure an IdM client to use the Kerberos Key Distribution Center Proxy (KKDCP) on an IdM server. This is useful if the default Kerberos ports are not accessible on the IdM server and the **HTTPS** port 443 is the only way of accessing the Kerberos service.

Prerequisites

• You have **root** access to the IdM client.

Procedure

- 1. Open the /etc/krb5.conf file for editing.
- In the `section, enter the URL of the KKDCP for the `kdc, admin_server, and kpasswd_server options:

```
[realms]
EXAMPLE.COM = {
  kdc = https://kdc.example.com/KdcProxy
  admin_server = https://kdc.example.com/KdcProxy
  kpasswd_server = https://kdc.example.com/KdcProxy
  default_domain = example.com
}
```

For redundancy, you can add the parameters **kdc**, **admin_server**, and **kpasswd_server** multiple times to indicate different KKDCP servers.

3. Restart the **sssd** service to make the changes take effect:

systemctl restart sssd

18.2. VERIFYING THAT KKDCP IS ENABLED ON AN IDM SERVER

On an Identity Management (IdM) server, the Kerberos Key Distribution Center Proxy (KKDCP) is automatically enabled each time the Apache web server starts if the attribute and value pair **ipaConfigString=kdcProxyEnabled** exists in the directory. In this situation, the symbolic link /etc/httpd/conf.d/ipa-kdc-proxy.conf is created.

You can verify if the KKDCP is enabled on the IdM server, even as an unprivileged user.

Procedure

• Check that the symbolic link exists:

\$ Is -I /etc/httpd/conf.d/ipa-kdc-proxy.conf

 $Irwxrwxrwx.\ 1\ root\ root\ 36\ Jun\ 21\ \ 2020\ /etc/httpd/conf.d/ipa-kdc-proxy.conf\ ->\ /etc/ipa/kdcproxy/ipa-kdc-proxy.conf$

The output confirms that KKDCP is enabled.

18.3. DISABLING KKDCP ON AN IDM SERVER

As an Identity Management (IdM) system administrator, you can disable the Kerberos Key Distribution Center Proxy (KKDCP) on an IdM server.

Prerequisites

• You have **root** access to the IdM server.

Procedure

1. Remove the **ipaConfigString=kdcProxyEnabled** attribute and value pair from the directory:

ipa-ldap-updater /usr/share/ipa/kdcproxy-disable.uldif

Update complete

The ipa-Idap-updater command was successful

2. Restart the httpd service:

systemctl restart httpd.service

KKDCP is now disabled on the current IdM server.

Verification

• Verify that the symbolic link does not exist:

\$ Is -I /etc/httpd/conf.d/ipa-kdc-proxy.conf

ls: cannot access '/etc/httpd/conf.d/ipa-kdc-proxy.conf': No such file or directory

18.4. RE-ENABLING KKDCP ON AN IDM SERVER

On an IdM server, the Kerberos Key Distribution Center Proxy (KKDCP) is enabled by default and available at https://<server.idm.example.com>/KdcProxy.

If KKDCP has been disabled on a server, you can re-enable it.

Prerequisites

• You have **root** access to the IdM server.

Procedure

1. Add the **ipaConfigString=kdcProxyEnabled** attribute and value pair to the directory:

ipa-Idap-updater /usr/share/ipa/kdcproxy-enable.uldif

Update complete

The ipa-Idap-updater command was successful

2. Restart the **httpd** service:

systemctl restart httpd.service

KKDCP is now enabled on the current IdM server.

Verification

• Verify that the symbolic link exists:

\$ Is -I /etc/httpd/conf.d/ipa-kdc-proxy.conf

lrwxrwxrwx. 1 root root 36 Jun 21 2020 /etc/httpd/conf.d/ipa-kdc-proxy.conf -> /etc/ipa/kdcproxy/ipa-kdc-proxy.conf

18.5. CONFIGURING THE KKDCP SERVER I

With the following configuration, you can enable TCP to be used as the transport protocol between the IdM KKDCP and the Active Directory (AD) realm, where multiple Kerberos servers are used.

Prerequisites

• You have **root** access.

Procedure

 Set the use_dns parameter in the `section of the `/etc/ipa/kdcproxy/kdcproxy.conf file to false.

```
[global]
use_dns = false
```

2. Put the proxied realm information into the /etc/ipa/kdcproxy/kdcproxy.conf file. For example, for the [AD.EXAMPLE.COM] realm with proxy list the realm configuration parameters as follows:

```
[AD.EXAMPLE.COM]
```

kerberos = kerberos+tcp://1.2.3.4:88 kerberos+tcp://5.6.7.8:88 kpasswd = kpasswd+tcp://1.2.3.4:464 kpasswd+tcp://5.6.7.8:464

IMPORTANT

The realm configuration parameters must list multiple servers separated by a space, as opposed to /etc/krb5.conf and kdc.conf, in which certain options may be specified multiple times.

3. Restart Identity Management (IdM) services:

ipactl restart

Additional resources

 Configure IPA server as a KDC Proxy for AD Kerberos communication (Red Hat Knowledgebase)

18.6. CONFIGURING THE KKDCP SERVER II

The following server configuration relies on the DNS service records to find Active Directory (AD) servers to communicate with.

Prerequisites

• You have root access.

Procedure

1. In the /etc/ipa/kdcproxy/kdcproxy.conf file, the `section, set the `use_dns parameter to true

```
[global]
configs = mit
use_dns = true
```

The **configs** parameter allows you to load other configuration modules. In this case, the configuration is read from the MIT **libkrb5** library.

2. Optional: In case you do not want to use DNS service records, add explicit AD servers to the `section of the `/etc/krb5.conf file. If the realm with proxy is, for example, AD. EXAMPLE.COM, you add:

```
[realms]
AD.EXAMPLE.COM = {
   kdc = ad-server.ad.example.com
   kpasswd_server = ad-server.ad.example.com
}
```

3. Restart Identity Management (IdM) services:

ipactl restart

Additional resources

 Configure IPA server as a KDC Proxy for AD Kerberos communication (Red Hat Knowledgebase)

CHAPTER 19. MANAGING SELF-SERVICE RULES IN IDM USING THE CLI

Learn about self-service rules in Identity Management (IdM) and how to create and edit self-service access rules on the command line (CLI).

19.1. SELF-SERVICE ACCESS CONTROL IN IDM

Self-service access control rules define which operations an Identity Management (IdM) entity can perform on its IdM Directory Server entry: for example, IdM users have the ability to update their own passwords.

This method of control allows an authenticated IdM entity to edit specific attributes within its LDAP entry, but does not allow **add** or **delete** operations on the entire entry.

WARNING

Be careful when working with self-service access control rules: configuring access control rules improperly can inadvertently elevate an entity's privileges.

19.2. CREATING SELF-SERVICE RULES USING THE CLI

Follow this procedure to create self-service access rules in IdM using the command line (CLI).

Prerequisites

- Administrator privileges for managing IdM or the **User Administrator** role.
- An active Kerberos ticket. For details, see Using kinit to log in to IdM manually .

Procedure

• To add a self-service rule, use the **ipa selfservice-add** command and specify the following two options:

--permissions

sets the read and write permissions the Access Control Instruction (ACI) grants.

--attrs

sets the complete list of attributes to which this ACI grants permission.

For example, to create a self-service rule allowing users to modify their own name details:

Self-service name: Users can manage their own name details

Permissions: write

Attributes: givenname, displayname, title, initials

19.3. EDITING SELF-SERVICE RULES USING THE CLI

Follow this procedure to edit self-service access rules in IdM using the command line (CLI).

Prerequisites

- Administrator privileges for managing IdM or the **User Administrator** role.
- An active Kerberos ticket. For details, see Using kinit to log in to IdM manually .

Procedure

- 1. Optional: Display existing self-service rules with the **ipa selfservice-find** command.
- 2. Optional: Display details for the self-service rule you want to modify with the **ipa selfservice-show** command.
- 3. Use the **ipa selfservice-mod** command to edit a self-service rule.

For example:

\$ ipa selfservice-mod "Users can manage their own name details" --attrs=givenname --attrs=title --attrs=initials --attrs=surname

Modified selfservice "Users can manage their own name details"

Self-service name: Users can manage their own name details

Permissions: write

Attributes: givenname, displayname, title, initials

IMPORTANT

Using the **ipa selfservice-mod** command overwrites the previously defined permissions and attributes, so always include the complete list of existing permissions and attributes along with any new ones you want to define.

Verification

• Use the **ipa selfservice-show** command to display the self-service rule you edited.

\$ ipa selfservice-show "Users can manage their own name details"

Self-service name: Users can manage their own name details

Permissions: write

Attributes: givenname, displayname, title, initials

19.4. DELETING SELF-SERVICE RULES USING THE CLI

Follow this procedure to delete self-service access rules in IdM using the command line (CLI).

Prerequisites

- Administrator privileges for managing IdM or the **User Administrator** role.
- An active Kerberos ticket. For details, see Using kinit to log in to IdM manually .

Procedure

• Use the **ipa selfservice-del** command to delete a self-service rule.

For example:

Verification

• Use the **ipa selfservice-find** command to display all self-service rules. The rule you just deleted should be missing.

CHAPTER 20. MANAGING SELF-SERVICE RULES USING THE IDM WEB UI

Learn about self-service rules in Identity Management (IdM) and how to create and edit self-service access rules in the web interface (IdM Web UI).

For general information about self-service access control in IdM, see Self-service access control in IdM section.

20.1. CREATING SELF-SERVICE RULES USING THE IDM WEB UI

Follow this procedure to create self-service access rules in IdM using the web interface (IdM Web UI).

Prerequisites

- Administrator privileges for managing IdM or the User Administrator role.
- You are logged-in to the IdM Web UI. For details, see Accessing the IdM Web UI in a web browser.

Procedure

- 1. Open the IPA Server>Role-Based Access Control menu and select Self Service Permissions.
- 2. Click **Add** at the upper-right of the list of the self-service access rules.
- 3. On the Add Self Service Permission window, enter the name of the new self-service rule in the Self-service name field. Spaces are allowed.
- 4. Select the checkboxes next to the attributes you want users to be able to edit.
- 5. Optional: If an attribute you want to provide access to is not listed, you can add a listing for it:
 - a. Click the Add button.
 - b. On the Add Custom Attribute window, enter the attribute name in the Attribute text field.
 - c. Click the **OK** button to add the attribute.
 - d. Verify that the new attribute is selected.
- 6. Click the **Add** button at the bottom of the form to save the new self-service rule.

 Alternatively, you can save and continue editing the self-service rule by clicking the **Add and Edit** button, or save and add further rules by clicking the **Add and Add another** button.

20.2. EDITING SELF-SERVICE RULES USING THE IDM WEB UI

Follow this procedure to edit self-service access rules in IdM using the web interface (IdM Web UI).

Prerequisites

• Administrator privileges for managing IdM or the **User Administrator** role.

 You are logged-in to the IdM Web UI. For details, see Accessing the IdM Web UI in a web browser.

Procedure

- 1. Open the IPA Server>Role-Based Access Control menu and select Self Service Permissions.
- 2. Click on the name of the self-service rule you want to modify.
- 3. The edit page only allows you to edit the list of attributes to you want to add or remove to the self-service rule. Select or deselect the appropriate checkboxes.
- 4. Click the **Save** button to save your changes to the self-service rule.

20.3. DELETING SELF-SERVICE RULES USING THE IDM WEB UI

Follow this procedure to delete self-service access rules in IdM using the web interface (IdM Web UI).

Prerequisites

- Administrator privileges for managing IdM or the **User Administrator** role.
- You are logged-in to the IdM Web UI. For details, see Accessing the IdM Web UI in a web browser.

Procedure

- 1. Open the IPA Server>Role-Based Access Control menu and select Self Service Permissions.
- 2. Select the checkbox next to the rule you want to delete, then click on the **Delete** button on the right of the list.
- 3. A dialog opens, click on **Delete** to confirm.

CHAPTER 21. USING ANSIBLE PLAYBOOKS TO MANAGE SELF-SERVICE RULES IN IDM

This section introduces self-service rules in Identity Management (IdM) and describes how to create and edit self-service access rules using Ansible playbooks. Self-service access control rules allow an IdM entity to perform specified operations on its IdM Directory Server entry.

21.1. USING ANSIBLE TO ENSURE THAT A SELF-SERVICE RULE IS PRESENT

The following procedure describes how to use an Ansible playbook to define self-service rules and ensure their presence on an Identity Management (IdM) server. In this example, the new **Users can manage their own name details** rule grants users the ability to change their own **givenname**, **displayname**, **title** and **initials** attributes. This allows them to, for example, change their display name or initials if they want to.

Prerequisites

- On the control node:
 - You are using Ansible version 2.15 or later.
 - You have installed the **freeipa.ansible freeipa** collection.
 - The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.
 - The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin_password** and that you have access to a file that stores the password protecting the **secret.yml** file.
- The target node, that is the node on which the **freeipa.ansible_freeipa** module is executed, is part of the IdM domain as an IdM client, server or replica.

Procedure

1. Navigate to the ~/MyPlaybooks/ directory:

\$ cd ~/MyPlaybooks/

 Make a copy of the selfservice-present.yml file located in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/selfs ervice/ directory:

\$ cp

/usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/se lfservice/selfservice-present.yml selfservice-present-copy.yml

- 3. Open the **selfservice-present-copy.yml** Ansible playbook file for editing.
- 4. Adapt the file by setting the following variables in the **freeipa.ansible_freeipa.ipaselfservice** task section:
 - Set the **name** variable to the name of the new self-service rule.

- Set the permission variable to a comma-separated list of permissions to grant: read and write
- Set the **attribute** variable to a list of attributes that users can manage themselves: **givenname**, **displayname**, **title**, and **initials**.

This is the modified Ansible playbook file for the current example:

- name: Self-service present

hosts: ipaserver

vars files:

- /home/user_name/MyPlaybooks/secret.yml

tasks:

- name: Ensure self-service rule "Users can manage their own name details" is present freeipa.ansible_freeipa.ipaselfservice:

ipaadmin_password: "{{ ipaadmin_password }}" name: "Users can manage their own name details" permission: read, write

attribute:

- givenname
- displayname
- title
- initials
- 5. Save the file.
- 6. Run the Ansible playbook. Specify the playbook file, the file storing the password protecting the **secret.yml** file, and the inventory file:

\$ ansible-playbook --vault-password-file=password_file -v -i inventory selfservice-present-copy.yml

Additional resources

- The **README-selfservice.md** file in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/ directory
- The /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/selfs ervice directory

21.2. USING ANSIBLE TO ENSURE THAT A SELF-SERVICE RULE IS ABSENT

The following procedure describes how to use an Ansible playbook to ensure a specified self-service rule is absent from your IdM configuration. The example below describes how to make sure the **Users can manage their own name details** self-service rule does not exist in IdM. This will ensure that users cannot, for example, change their own display name or initials.

Prerequisites

• On the control node:

- You are using Ansible version 2.15 or later.
- You have installed the freeipa.ansible freeipa collection.
- The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.
- The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin_password** and that you have access to a file that stores the password protecting the **secret.yml** file.
- The target node, that is the node on which the **freeipa.ansible_freeipa** module is executed, is part of the IdM domain as an IdM client, server or replica.

Procedure

1. Navigate to the ~/MyPlaybooks/ directory:

\$ cd ~/MyPlaybooks/

 Make a copy of the selfservice-absent.yml file located in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/selfs ervice/ directory:

\$ cp

/usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/se lfservice/selfservice-absent.yml selfservice-absent-copy.yml

- 3. Open the **selfservice-absent-copy.yml** Ansible playbook file for editing.
- 4. Adapt the file by setting the following variables in the **freeipa.ansible_freeipa.ipaselfservice** task section:
 - Set the **name** variable to the name of the self-service rule.
 - Set the **state** variable to **absent**.

This is the modified Ansible playbook file for the current example:

- name: Self-service absent

hosts: ipaserver

vars files:

- /home/user_name/MyPlaybooks/secret.yml

- name: Ensure self-service rule "Users can manage their own name details" is absent freeipa.ansible_freeipa.ipaselfservice:

ipaadmin_password: "{{ ipaadmin_password }}"
name: "Users can manage their own name details"

state: absent

- 5. Save the file.
- 6. Run the Ansible playbook. Specify the playbook file, the file storing the password protecting the **secret.yml** file, and the inventory file:

-

\$ ansible-playbook --vault-password-file=password_file -v -i inventory selfservice-absent-copy.yml

Additional resources

- Self-service access control in IdM
- The **README-selfservice.md** file in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/ directory
- Sample playbooks in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/selfs ervice directory

21.3. USING ANSIBLE TO ENSURE THAT A SELF-SERVICE RULE HAS SPECIFIC ATTRIBUTES

The following procedure describes how to use an Ansible playbook to ensure that an already existing self-service rule has specific settings. In the example, you ensure the **Users can manage their own name details** self-service rule also has the **surname** member attribute.

Prerequisites

- On the control node:
 - You are using Ansible version 2.15 or later.
 - You have installed the **freeipa.ansible_freeipa** collection.
 - The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.
 - The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin_password** and that you have access to a file that stores the password protecting the **secret.yml** file.
- The target node, that is the node on which the **freeipa.ansible_freeipa** module is executed, is part of the IdM domain as an IdM client, server or replica.
- The Users can manage their own name details elf-service rule exists in IdM.

Procedure

1. Navigate to the ~/MyPlaybooks/ directory:

\$ cd ~/MyPlaybooks/

 Make a copy of the selfservice-member-present.yml file located in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/selfs ervice/ directory:

\$ cp

/usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/se Ifservice/selfservice-member-present.yml selfservice-member-present-copy.yml

- 3. Open the **selfservice-member-present-copy.yml** Ansible playbook file for editing.
- 4. Adapt the file by setting the following variables in the **freeipa.ansible_freeipa.ipaselfservice** task section:
 - Set the **name** variable to the name of the self-service rule to modify.
 - Set the **attribute** variable to **surname**.
 - Set the action variable to member.

This is the modified Ansible playbook file for the current example:

- name: Self-service member present

hosts: ipaserver

vars_files:

- /home/user_name/MyPlaybooks/secret.yml

tasks:

- name: Ensure selfservice "Users can manage their own name details" member attribute surname is present

freeipa.ansible_freeipa.ipaselfservice:

ipaadmin_password: "{{ ipaadmin_password }}"

name: "Users can manage their own name details"

attribute:

- surname

action: member

- 5. Save the file.
- 6. Run the Ansible playbook. Specify the playbook file, the file storing the password protecting the **secret.yml** file, and the inventory file:

\$ ansible-playbook --vault-password-file=password_file -v -i inventory selfservice-member-present-copy.yml

Additional resources

- Self-service access control in IdM
- The **README-selfservice.md** file available in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/ directory
- The sample playbooks in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/selfs ervice directory

21.4. USING ANSIBLE TO ENSURE THAT A SELF-SERVICE RULE DOES NOT HAVE SPECIFIC ATTRIBUTES

The following procedure describes how to use an Ansible playbook to ensure that a self-service rule does not have specific settings. You can use this playbook to make sure a self-service rule does not grant undesired access. In the example, you ensure the **Users can manage their own name details**self-service rule does not have the **givenname** and **surname** member attributes.

Prerequisites

- On the control node:
 - You are using Ansible version 2.15 or later.
 - You have installed the freeipa.ansible_freeipa collection.
 - The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.
 - The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin_password** and that you have access to a file that stores the password protecting the **secret.yml** file.
- The target node, that is the node on which the **freeipa.ansible_freeipa** module is executed, is part of the IdM domain as an IdM client, server or replica.
- The Users can manage their own name detailself-service rule exists in IdM.

Procedure

1. Navigate to the ~/MyPlaybooks/ directory:

\$ cd ~/MyPlaybooks/

 Make a copy of the selfservice-member-absent.yml file located in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/selfs ervice/ directory:

\$ cp

/usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/se lfservice/selfservice-member-absent.yml selfservice-member-absent-copy.yml

- 3. Open the **selfservice-member-absent-copy.yml** Ansible playbook file for editing.
- 4. Adapt the file by setting the following variables in the **freeipa.ansible_freeipa.ipaselfservice** task section:
 - Set the name variable to the name of the self-service rule you want to modify.
 - Set the attribute variable to givenname and surname.
 - Set the action variable to member.
 - Set the **state** variable to **absent**.

This is the modified Ansible playbook file for the current example:

- name: Self-service member absent

hosts: ipaserver

vars files:

- /home/user_name/MyPlaybooks/secret.yml

- name: Ensure selfservice "Users can manage their own name details" member attributes

givenname and surname are absent

freeipa.ansible_freeipa.ipaselfservice:

ipaadmin_password: "{{ ipaadmin_password }}"
name: "Users can manage their own name details"

attribute:

- givenname

- surname

action: member state: absent

- 5. Save the file.
- 6. Run the Ansible playbook. Specify the playbook file, the file storing the password protecting the **secret.yml** file, and the inventory file:

\$ ansible-playbook --vault-password-file=password_file -v -i inventory selfservice-member-absent-copy.yml

Additional resources

- Self-service access control in IdM
- The **README-selfservice.md** file in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/ directory
- The sample playbooks in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/selfs ervice directory

CHAPTER 22. MANAGING USER GROUPS IN IDM CLI

Learn about user groups management using the IdM CLI. A user group is a set of users with common privileges, password policies, and other characteristics.

A user group in Identity Management (IdM) can include:

- IdM users
- other IdM user groups
- external users, which are users that exist outside of IdM

22.1. THE DIFFERENT GROUP TYPES IN IDM

IdM supports the following types of groups:

POSIX groups (the default)

POSIX groups support Linux POSIX attributes for their members. Note that groups that interact with Active Directory cannot use POSIX attributes.

POSIX attributes identify users as separate entities. Examples of POSIX attributes relevant to users include **uidNumber**, a user number (UID), and **gidNumber**, a group number (GID).

Non-POSIX groups

Non-POSIX groups do not support POSIX attributes. For example, these groups do not have a GID defined.

All members of this type of group must belong to the IdM domain.

External groups

Use external groups to add group members that exist in an identity store outside of the IdM domain, such as:

- A local system
- An Active Directory domain
- A directory service

External groups do not support POSIX attributes. For example, these groups do not have a GID defined.

Table 22.1. User groups created by default

Group name	Default group members
ipausers	All IdM users
admins	Users with administrative privileges, including the default admin user
editors	This is a legacy group that no longer has any special privileges

Group name	Default group members
trust admins	Users with privileges to manage the Active Directory trusts

When you add a user to a user group, the user gains the privileges and policies associated with the group. For example, to grant administrative privileges to a user, add the user to the **admins** group.

WARNING

Do not delete the **admins** group. As **admins** is a pre-defined group required by IdM, this operation causes problems with certain commands.

In addition, IdM creates *user private groups* by default whenever a new user is created in IdM. For more information about private groups, see Adding users without a private group.

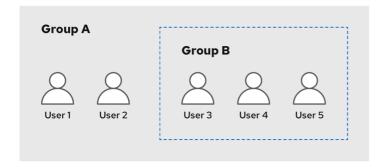

22.2. DIRECT AND INDIRECT GROUP MEMBERS

User group attributes in IdM apply to both direct and indirect members: when group B is a member of group A, all users in group B are considered indirect members of group A.

For example, in the following diagram:

- User 1 and User 2 are *direct members* of group A.
- User 3, User 4, and User 5 are indirect members of group A.

Figure 22.1. Direct and Indirect Group Membership

640_RHEL_0424

If you set a password policy for user group A, the policy also applies to all users in user group B.

22.3. ADDING A USER GROUP USING IDM CLI

Follow this procedure to add a user group using the IdM CLI.

Prerequisites

You must be logged in as the administrator. For details, see Using kinit to log in to IdM manually .

Procedure

 Add a user group by using the ipa group-add group_name command. For example, to create group_a:

```
$ ipa group-add group_a
-----
Added group "group_a"
-----
Group name: group_a
GID: 1133400009
```

By default, **ipa group-add** adds a POSIX user group. To specify a different group type, add options to **ipa group-add**:

- --nonposix to create a non-POSIX group
- --external to create an external group

For details on group types, see The different group types in IdM.

You can specify a custom GID when adding a user group by using the **--gid=***custom_GID* option. If you do this, be careful to avoid ID conflicts. If you do not specify a custom GID, IdM automatically assigns a GID from the available ID range.

22.4. SEARCHING FOR USER GROUPS USING IDM CLI

Follow this procedure to search for existing user groups using the IdM CLI.

Procedure

- Display all user groups by using the ipa group-find command. To specify a group type, add options to ipa group-find:
 - Display all POSIX groups using the **ipa group-find --posix** command.
 - Display all non-POSIX groups using the **ipa group-find --nonposix** command.
 - Display all external groups using the **ipa group-find --external** command.

For more information about different group types, see The different group types in IdM.

22.5. DELETING A USER GROUP USING IDM CLI

Follow this procedure to delete a user group using IdM CLI. Note that deleting a group does not delete the group members from IdM.

Prerequisites

You must be logged in as the administrator. For details, see Using kinit to log in to IdM manually.

Procedure

• Delete a user group by using the **ipa group-del group_name** command. For example, to delete group_a:

\$ ipa group-del group_a
----Deleted group "group_a"

22.6. ADDING A MEMBER TO A USER GROUP USING IDM CLI

You can add both users and user groups as members of a user group. For more information, see The different group types in IdM and Direct and indirect group members. Follow this procedure to add a member to a user group by using the IdM CLI.

Prerequisites

• You must be logged in as the administrator. For details, see Using kinit to log in to IdM manually .

Procedure

- Add a member to a user group by using the **ipa group-add-member** command. Specify the type of member using these options:
 - --users adds an IdM user
 - --external adds a user that exists outside the IdM domain, in the format of DOMAIN\user name or user name@domain
 - --groups adds an IdM user group

For example, to add group_b as a member of group_a:

\$ ipa group-add-member group_a --groups=group_b
Group name: group_a
GID: 1133400009
Member users: user_a
Member groups: group_b
Indirect Member users: user_b

Number of members added 1

Members of group_b are now indirect members of group_a.

IMPORTANT

When adding a group as a member of another group, do not create recursive groups. For example, if Group A is a member of Group B, do not add Group B as a member of Group A. Recursive groups can cause unpredictable behavior.

NOTE

After you add a member to a user group, the update may take some time to spread to all clients in your Identity Management environment. This is because when any given host resolves users, groups and netgroups, the **System Security Services Daemon** (SSSD) first looks into its cache and performs server lookups only for missing or expired records.

22.7. ADDING USERS WITHOUT A USER PRIVATE GROUP

By default, IdM creates user private groups (UPGs) whenever a new user is created in IdM. UPGs are a specific group type:

- The UPG has the same name as the newly created user.
- The user is the only member of the UPG. The UPG cannot contain any other members.
- The GID of the private group matches the UID of the user.

However, it is possible to add users without creating a UPG.

22.7.1. Users without a user private group

If a NIS group or another system group already uses the GID that would be assigned to a user private group, it is necessary to avoid creating a UPG.

You can do this in two ways:

- Add a new user without a UPG, without disabling private groups globally. See Adding a user without a user private group when private groups are globally enabled.
- Disable UPGs globally for all users, then add a new user. See Disabling user private groups globally for all users and Adding a user when user private groups are globally disabled.

In both cases, IdM will require specifying a GID when adding new users, otherwise the operation will fail. This is because IdM requires a GID for the new user, but the default user group **ipausers** is a non-POSIX group and therefore does not have an associated GID. The GID you specify does not have to correspond to an already existing group.

NOTE

Specifying the GID does not create a new group. It only sets the GID attribute for the new user, because the attribute is required by IdM.

22.7.2. Adding a user without a user private group when private groups are globally enabled

You can add a user without creating a user private group (UPG) even when UPGs are enabled on the system. This requires manually setting a GID for the new user. For details on why this is needed, see Users without a user private group.

Procedure

 To prevent IdM from creating a UPG, add the --noprivate option to the ipa user-add command.

Note that for the command to succeed, you must specify a custom GID. For example, to add a new user with GID 10000:

\$ ipa user-add jsmith --first=John --last=Smith --noprivate --gid 10000

22.7.3. Disabling user private groups globally for all users

You can disable user private groups (UPGs) globally. This prevents the creation of UPGs for all new users. Existing users are unaffected by this change.

Procedure

1. Obtain administrator privileges:

\$ kinit admin

2. IdM uses the Directory Server Managed Entries Plug-in to manage UPGs. List the instances of the plug-in:

\$ ipa-managed-entries --list

3. To ensure IdM does not create UPGs, disable the plug-in instance responsible for managing user private groups:

\$ ipa-managed-entries -e "UPG Definition" disable Disabling Plugin

To re-enable the **UPG Definition** instance later, use the **ipa-managed-entries -e "UPG Definition" enable** command.

4. Restart Directory Server to load the new configuration.

\$ sudo systemctl restart dirsrv.target

To add a user after UPGs have been disabled, you need to specify a GID. For more information, see Adding a user when user private groups are globally disabled

Verification

• To check if UPGs are globally disabled, use the disable command again:

\$ ipa-managed-entries -e "UPG Definition" disable Plugin already disabled

22.7.4. Adding a user when user private groups are globally disabled

When user private groups (UPGs) are disabled globally, IdM does not assign a GID to a new user automatically. To successfully add a user, you must assign a GID manually or by using an automember rule. For details on why this is required, see Users without a user private group.

Prerequisites

 UPGs must be disabled globally for all users. For more information, see Disabling user private groups globally for all users

Procedure

- To make sure adding a new user succeeds when creating UPGs is disabled, choose one of the following:
 - Specify a custom GID when adding a new user. The GID does not have to correspond to an

already existing user group.

For example, when adding a user from the command line, add the **--gid** option to the **ipa user-add** command.

• Use an automember rule to add the user to an existing group with a GID.

22.8. ADDING USERS OR GROUPS AS MEMBER MANAGERS TO AN IDM USER GROUP USING THE IDM CLI

Follow this procedure to add users or groups as member managers to an IdM user group using the IdM CLI. Member managers can add users or groups to IdM user groups but cannot change the attributes of a group.

Prerequisites

- You must be logged in as the administrator. For details, see Using kinit to log in to IdM manually .
- You must have the name of the user or group you are adding as member managers and the name of the group you want them to manage.

Procedure

• Add a user as a member manager to an IdM user group by using the **ipa group-add-member-manager** command.

For example, to add the user **test** as a member manager of **group_a**:

\$ ipa group-add-member-manager group_a --users=test
Group name: group_a
GID: 1133400009
Membership managed by users: test
----Number of members added 1

User **test** can now manage members of **group_a**.

Add a group as a member manager to an IdM user group by using the ipa group-add-member-manager command.

For example, to add the group **group admins** as a member manager of **group a**:

\$ ipa group-add-member-manager group_a --groups=group_admins
Group name: group_a
GID: 1133400009
Membership managed by groups: group_admins
Membership managed by users: test
-----Number of members added 1

Group **group_admins** can now manage members of **group_a**.

NOTE

After you add a member manager to a user group, the update may take some time to spread to all clients in your Identity Management environment.

Verification

 Using the ipa group-show command to verify the user and group were added as member managers.

\$ ipa group-show group_a

Group name: group_a GID: 1133400009

Membership managed by groups: group_admins

Membership managed by users: test

Additional resources

• See **ipa group-add-member-manager --help** for more details.

22.9. VIEWING GROUP MEMBERS USING IDM CLI

Follow this procedure to view members of a group using IdM CLI. You can view both direct and indirect group members. For more information, see Direct and indirect group members.

Procedure

• To list members of a group, use the **ipa group-show group_name** command. For example:

\$ ipa group-show group_a

...

Member users: user_a Member groups: group_b Indirect Member users: user_b

NOTE

The list of indirect members does not include external users from trusted Active Directory domains. The Active Directory trust user objects are not visible in the Identity Management interface because they do not exist as LDAP objects within Identity Management.

22.10. REMOVING A MEMBER FROM A USER GROUP USING IDM CLI

Follow this procedure to remove a member from a user group using IdM CLI.

Prerequisites

• You must be logged in as the administrator. For details, see Using kinit to log in to IdM manually .

Procedure

- 1. Optional: Use the **ipa group-show** command to confirm that the group includes the member you want to remove.
- 2. Remove a member from a user group by using the **ipa group-remove-member** command. Specify members to remove using these options:
 - --users removes an IdM user
 - --external removes a user that exists outside the IdM domain, in the format of DOMAIN\user_name or user_name@domain
 - --groups removes an IdM user group

For example, to remove user1, user2, and group1 from a group called group_name:

\$ ipa group-remove-member pass:quotes[group_name] --users=pass:quotes[user1] --users=pass:quotes[user2] --groups=pass:quotes[group1]

22.11. REMOVING USERS OR GROUPS AS MEMBER MANAGERS FROM AN IDM USER GROUP USING THE IDM CLI

Follow this procedure to remove users or groups as member managers from an IdM user group using the IdM CLI. Member managers can remove users or groups from IdM user groups but cannot change the attributes of a group.

Prerequisites

- You must be logged in as the administrator. For details, see Using kinit to log in to IdM manually .
- You must have the name of the existing member manager user or group you are removing and the name of the group they are managing.

Procedure

• Remove a user as a member manager of an IdM user group by using the **ipa group-remove-member-manager** command.

For example, to remove the user **test** as a member manager of **group_a**:

\$ ipa group-remove-member-manager group_a --users=test
Group name: group_a
GID: 1133400009
Membership managed by groups: group_admins
----Number of members removed 1

User **test** can no longer manage members of **group_a**.

• Remove a group as a member manager of an IdM user group by using the **ipa group-remove-member-manager** command.

For example, to remove the group **group_admins** as a member manager of **group_a**:

\$ ipa group-remove-member-manager group_a --groups=group_admins
Group name: group_a

GID: 1133400009
----Number of members removed 1

Group group_admins can no longer manage members of group_a.

NOTE

After you remove a member manager from a user group, the update may take some time to spread to all clients in your Identity Management environment.

Verification

• Using the **ipa group-show** command to verify the user and group were removed as member managers.

\$ ipa group-show group_a Group name: group_a GID: 1133400009

Additional resources

• See ipa group-remove-member-manager --help for more details.

22.12. ENABLING GROUP MERGING FOR LOCAL AND REMOTE GROUPS IN IDM

Groups are either centrally managed, provided by a domain such as Identity Management (IdM) or Active Directory (AD), or they are managed on a local system in the **etc/group** file. In most cases, users rely on a centrally managed store. However, in some cases software still relies on membership in known groups for managing access control.

If you want to manage groups from a domain controller and from the local **etc/group** file, you can enable group merging. You can configure your **nsswitch.conf** file to check both the local files and the remote service. If a group appears in both, the list of member users is combined and returned in a single response.

The steps below describe how to enable group merging for a user, idmuser.

NOTE

If you are using the **authselect** utility, you no longer need to manually edit **nssswitch.conf** to enable group merging. It is now integrated into **authselect** profiles, eliminating the need for manual changes.

Procedure

1. Add [SUCCESS=merge] to the /etc/nsswitch.conf file:

Allow initgroups to default to the setting for group. initgroups: sss [SUCCESS=merge] files

2. Add the idmuser to IdM:

ipa user-add idmuser

First name: idm Last name: user

Added user "idmuser"

User login: idmuser
First name: idm
Last name: user
Full name: idm user
Display name: idm user

Initials: tu

Home directory: /home/idmuser

GECOS: idm user Login shell: /bin/sh

Principal name: idmuser@IPA.TEST Principal alias: idmuser@IPA.TEST Email address: idmuser@ipa.test

UID: 19000024 GID: 19000024 Password: False

Member of groups: ipausers Kerberos keys available: False

3. Verify the GID of the local **audio** group.

\$ getent group audio

audio:x:63

4. Add the group **audio** to IdM:

\$ ipa group-add audio --gid 63

Added group "audio"

Group name: audio

GID: 63

NOTE

The GID you define when adding the **audio** group to IdM must be the same as the GID of the local **audio** group.

5. Add *idmuser* user to the IdM **audio** group:

\$ ipa group-add-member audio --users=idmuser

Group name: audio

GID: 63

Member users: idmuser

Number of members added 1

Verification

- 1. Log in as the *idmuser*.
- 2. Verify the *idmuser* has the local group in their session:

\$ id idmuser uid=1867800003(idmuser) gid=1867800003(idmuser) groups=1867800003(idmuser),63(audio),10(wheel)

Additional resources

• Using Ansible to give a user ID override access to the local sound card on an IdM client

CHAPTER 23. MANAGING USER GROUPS IN IDM WEB UI

This chapter introduces user groups management using the IdM web UI.

A user group is a set of users with common privileges, password policies, and other characteristics.

A user group in Identity Management (IdM) can include:

- IdM users
- other IdM user groups
- external users, which are users that exist outside of IdM

For details about the group types in IdM, see The different group types in IdM section. For details about direct and indirect group members, see Direct and indirect group members section.

23.1. ADDING A USER GROUP USING IDM WEB UI

Follow this procedure to add a user group using the IdM Web UI.

Prerequisites

• You are logged in to the IdM Web UI.

Procedure

- 1. Click **Identity** → **Groups**, and select **User Groups** in the left sidebar.
- 2. Click **Add** to start adding the group.
- 3. Fill out the information about the group. For more information about user group types, see The different group types in IdM.
 - You can specify a custom GID for the group. If you do this, be careful to avoid ID conflicts. If you do not specify a custom GID, IdM automatically assigns a GID from the available ID range.
- 4. Click Add to confirm.

23.2. DELETING A USER GROUP USING IDM WEB UI

Follow this procedure to delete a user group using the IdM Web UI. Note that deleting a group does not delete the group members from IdM.

Prerequisites

You are logged in to the IdM Web UI.

Procedure

- 1. Click Identity → Groups and select User Groups.
- 2. Select the group to delete.
- 3. Click Delete.

4. Click **Delete** to confirm.

23.3. ADDING A MEMBER TO A USER GROUP USING IDM WEB UI

You can add both users and user groups as members of a user group. For more information, see The different group types in IdM and Direct and indirect group members.

Prerequisites

• You are logged in to the IdM Web UI.

Procedure

- 1. Click **Identity** → **Groups** and select **User Groups** in the left sidebar.
- 2. Click the name of the group.
- 3. Select the type of group member you want to add: Users, User Groups, or External.
- 4. Click Add.
- 5. Select the checkbox next to one or more members you want to add.
- 6. Click the right arrow to move the selected members to the group.
- 7. Click Add to confirm.

23.4. ADDING USERS OR GROUPS AS MEMBER MANAGERS TO AN IDM USER GROUP USING THE WEB UI

Follow this procedure to add users or groups as member managers to an IdM user group using the Web UI. Member managers can add users or groups to IdM user groups but cannot change the attributes of a group.

Prerequisites

- You are logged in to the IdM Web UI.
- You must have the name of the user or group you are adding as member managers and the name of the group you want them to manage.

Procedure

- 1. Click **Identity** → **Groups** and select **User Groups** in the left sidebar.
- 2. Click the name of the group.
- 3. Select the type of group member manager you want to add: Users or User Groups.
- 4. Click Add.
- 5. Select the checkbox next to one or more members you want to add.
- 6. Click the right arrow to move the selected members to the group.

7. Click Add to confirm.

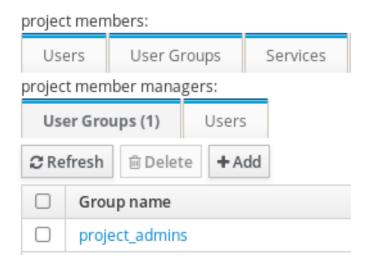

NOTE

After you add a member manager to a user group, the update may take some time to spread to all clients in your Identity Management environment.

Verification

• Verify the newly added user or user group has been added to the member manager list of users or user groups:

User Group: project

Additional resources

• See **ipa group-add-member-manager --help** for more information.

23.5. VIFWING GROUP MEMBERS USING IDM WEB UI

Follow this procedure to view members of a group using the IdM Web UI. You can view both direct and indirect group members. For more information, see Direct and indirect group members.

Prerequisites

• You are logged in to the IdM Web UI.

Procedure

- 1. Select Identity → Groups.
- 2. Select **User Groups** in the left sidebar.
- 3. Click the name of the group you want to view.
- 4. Switch between **Direct Membership** and **Indirect Membership**.

23.6. REMOVING A MEMBER FROM A USER GROUP USING IDM WEB UI

Follow this procedure to remove a member from a user group using the IdM Web UI.

Prerequisites

• You are logged in to the IdM Web UI.

Procedure

- 1. Click **Identity** → **Groups** and select **User Groups** in the left sidebar.
- 2. Click the name of the group.
- 3. Select the type of group member you want to remove: Users, User Groups, or External.
- 4. Select the checkbox next to the member you want to remove.
- 5. Click Delete.
- 6. Click **Delete** to confirm.

23.7. REMOVING USERS OR GROUPS AS MEMBER MANAGERS FROM AN IDM USER GROUP USING THE WEB UI

Follow this procedure to remove users or groups as member managers from an IdM user group using the Web UI. Member managers can remove users or groups from IdM user groups but cannot change the attributes of a group.

Prerequisites

- You are logged in to the IdM Web UI.
- You must have the name of the existing member manager user or group you are removing and the name of the group they are managing.

Procedure

- 1. Click **Identity** → **Groups** and select **User Groups** in the left sidebar.
- 2. Click the name of the group.
- 3. Select the type of member manager you want to remove: Users or User Groups.
- 4. Select the checkbox next to the member manager you want to remove.
- 5. Click **Delete**.
- 6. Click Delete to confirm.

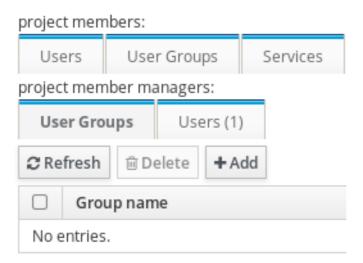

NOTE

After you remove a member manager from a user group, the update may take some time to spread to all clients in your Identity Management environment.

Verification

• Verify the user or user group has been removed from the member manager list of users or user groups:

User Group: project

Additional resources

• See **ipa group-add-member-manager --help** for more details.

CHAPTER 24. MANAGING USER GROUPS USING ANSIBLE PLAYBOOKS

This section introduces user group management using Ansible playbooks.

A user group is a set of users with common privileges, password policies, and other characteristics.

A user group in Identity Management (IdM) can include:

- IdM users
- other IdM user groups
- external users, which are users that exist outside of IdM

24.1. ENSURING THE PRESENCE OF IDM GROUPS AND GROUP MEMBERS USING ANSIBLE PLAYBOOKS

The following procedure describes ensuring the presence of IdM groups and group members - both users and user groups - using an Ansible playbook.

Prerequisites

- You have configured your Ansible control node to meet the following requirements:
 - You are using Ansible version 2.15 or later.
 - You have installed the **freeipa.ansible_freeipa** collection.
 - The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.
 - The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin_password** and that you have access to a file that stores the password protecting the **secret.yml** file.
- The target node, that is the node on which the **freeipa.ansible_freeipa** module is executed, is part of the IdM domain as an IdM client, server or replica.
- The users you want to reference in your Ansible playbook exist in IdM. For details on ensuring the presence of users using Ansible, see Managing user accounts using Ansible playbooks.

Procedure

1. Create an Ansible playbook file with the necessary user and group information:

- name: Playbook to handle groups

hosts: ipaserver

vars files:

- /home/user_name/MyPlaybooks/secret.yml tasks:

 name: Create group ops with gid 1234 freeipa.ansible_freeipa.ipagroup:

ipaadmin password: "{{ ipaadmin password }}"

```
name: ops
  gidnumber: 1234
- name: Create group sysops
 freeipa.ansible freeipa.ipagroup:
  ipaadmin_password: "{{ ipaadmin_password }}"
  name: sysops
  user:
  - idm user
- name: Create group appops
 freeipa.ansible_freeipa.ipagroup:
  ipaadmin_password: "{{ ipaadmin_password }}"
  name: appops
- name: Add group members sysops and appops to group ops
 freeipa.ansible_freeipa.ipagroup:
  ipaadmin_password: "{{ ipaadmin_password }}"
  name: ops
  group:
  - sysops
  - appops
```

2. Run the playbook:

\$ ansible-playbook --vault-password-file=password_file -v -i path_to_inventory_directory/inventory.file path_to_playbooks_directory/add-groupmembers.yml

Verification

You can verify if the **ops** group contains **sysops** and **appops** as direct members and **idm_user** as an indirect member by using the **ipa group-show** command:

1. Log into **ipaserver** as administrator:

```
$ ssh admin@server.idm.example.com
Password:
[admin@server/]$
```

2. Display information about ops:

```
ipaserver]$ ipa group-show ops
Group name: ops
GID: 1234
Member groups: sysops, appops
Indirect Member users: idm_user
```

The appops and sysops groups - the latter including the idm_user user - exist in IdM.

Additional resources

 See the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/README-group.md Markdown file.

24.2. USING ANSIBLE TO ADD MULTIPLE IDM GROUPS IN A SINGLE TASK

You can use the **ansible-freeipa ipagroup** module to add, modify, and delete multiple Identity Management (IdM) user groups with a single Ansible task. For that, use the **groups** option of the **ipagroup** module.

Using the **groups** option, you can also specify multiple group variables that only apply to a particular group. Define this group by the **name** variable, which is the only mandatory variable for the **groups** option.

Complete this procedure to ensure the presence of the **sysops** and the **appops** groups in IdM in a single task. Define the sysops group as a nonposix group and the appops group as an external group.

Prerequisites

- On the control node:
 - You are using Ansible version 2.15 or later.
 - You have installed the **freeipa.ansible_freeipa** collection.
 - The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.
 - The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin_password** and that you have access to a file that stores the password protecting the **secret.yml** file.
- The target node, that is the node on which the **freeipa.ansible_freeipa** module is executed, is part of the IdM domain as an IdM client, server or replica.

Procedure

1. Create your Ansible playbook file **add-nonposix-and-external-groups.yml** with the following content:

--

- name: Playbook to add nonposix and external groups

hosts: ipaserver vars files:

- /home/user_name/MyPlaybooks/secret.yml

tasks:

- name: Add nonposix group sysops and external group appops freeipa.ansible freeipa.ipagroup:

ipaadmin_password: "{{ ipaadmin_password }}"
groups:

name: sysops nonposix: truename: appops external: true

2. Run the playbook:

\$ ansible-playbook --vault-password-file=password_file -v -i <path_to_inventory_directory>/hosts <path_to_playbooks_directory>/add-nonposix-and-external-groups.yml

Additional resources

• The group module in **ansible-freeipa** upstream docs

24.3. USING ANSIBLE TO ENABLE AD USERS TO ADMINISTER IDM

Follow this procedure to use an Ansible playbook to ensure that a user ID override is present in an Identity Management (IdM) group. The user ID override is the override of an {AD} (AD) user that you created in the Default Trust View after you established a trust with AD. As a result of running the playbook, an AD user, for example an AD administrator, is able to fully administer IdM without having two different accounts and passwords.

Prerequisites

- You know the IdM **admin** password.
- You have installed a trust with AD.
- The user ID override of the AD user already exists in IdM. If it does not, create it with the **ipa idoverrideuser-add 'default trust view' ad_user@ad.example.com** command.
- The group to which you are adding the user ID override already exists in IdM .
- You are using the 4.8.7 version of IdM or later. To view the version of IdM you have installed on your server, enter **ipa --version**.
- You have configured your Ansible control node to meet the following requirements:
 - You are using Ansible version 2.15 or later.
 - You have installed the **freeipa.ansible_freeipa** collection.
 - The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.
 - The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin_password** and that you have access to a file that stores the password protecting the **secret.yml** file.
- The target node, that is the node on which the **freeipa.ansible_freeipa** module is executed, is part of the IdM domain as an IdM client, server or replica.

Procedure

1. Navigate to your ~/MyPlaybooks/ directory:

\$ cd ~/MyPlaybooks/

2. Create an **add-useridoverride-to-group.yml** playbook with the following content:

--- - name: Playbook to ensure presence of users in a group

hosts: ipaserver

tasks:

- name: Ensure the ad_user@ad.example.com user ID override is a member of the admins

freeipa.ansible_freeipa.ipagroup:

ipaadmin password: "{{ ipaadmin password }}"

name: admins idoverrideuser:

- ad user@ad.example.com

In the example:

- admins is the name of the IdM POSIX group to which you are adding the ad_user@ad.example.com ID override. Members of this group have full administrator privileges.
- ad_user@ad.example.com is the user ID override of an AD administrator. The user is stored in the AD domain with which a trust has been established.
- 3. Save the file.
- 4. Run the Ansible playbook. Specify the playbook file, the file storing the password protecting the **secret.yml** file, and the inventory file:

\$ ansible-playbook --vault-password-file=password_file -v -i inventory add-useridoverride-to-group.yml

Additional resources

- ID overrides for AD users
- /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/README-group.md
- /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/user
- Using ID views in Active Directory environments
- Enabling AD users to administer IdM

24.4. ENSURING THE PRESENCE OF MEMBER MANAGERS IN IDM USER GROUPS USING ANSIBLE PLAYBOOKS

The following procedure describes ensuring the presence of IdM member managers - both users and user groups - using an Ansible playbook.

Prerequisites

- On the control node:
 - You are using Ansible version 2.15 or later.
 - You have installed the **freeipa.ansible freeipa** collection.

- The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.
- The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin_password** and that you have access to a file that stores the password protecting the **secret.yml** file.
- The target node, that is the node on which the **freeipa.ansible_freeipa** module is executed, is part of the IdM domain as an IdM client, server or replica.
- You must have the name of the user or group you are adding as member managers and the name of the group you want them to manage.

Procedure

1. Create an Ansible playbook file with the necessary user and group member management information:

```
-name: Playbook to handle membership management hosts: ipaserver

vars_files:
-/home/user_name/MyPlaybooks/secret.yml tasks:
-name: Ensure user test is present for group_a freeipa.ansible_freeipa.ipagroup:
    ipaadmin_password: "{{ ipaadmin_password }}"
    name: group_a
    membermanager_user: test

-name: Ensure group_admins is present for group_a freeipa.ansible_freeipa.ipagroup:
    ipaadmin_password: "{{ ipaadmin_password }}"
    name: group_a
    membermanager_group: group_admins
```

2. Run the playbook:

\$ ansible-playbook --vault-password-file=password_file -v -i path_to_inventory_directory/inventory.file path_to_playbooks_directory/add-member-managers-user-groups.yml

Verification

You can verify if the **group_a** group contains **test** as a member manager and **group_admins** is a member manager of **group_a** by using the **ipa group-show** command:

1. Log into **ipaserver** as administrator:

```
$ ssh admin@server.idm.example.com
Password:
[admin@server/]$
```

2. Display information about managergroup1:

ipaserver]\$ ipa group-show group a

Group name: group_a GID: 1133400009

Membership managed by groups: group_admins

Membership managed by users: test

Additional resources

- See ipa host-add-member-manager --help.
- See the **ipa** man page on your system.

24.5. ENSURING THE ABSENCE OF MEMBER MANAGERS IN IDM USER GROUPS USING ANSIBLE PLAYBOOKS

The following procedure describes ensuring the absence of IdM member managers - both users and user groups - using an Ansible playbook.

Prerequisites

- On the control node:
 - You are using Ansible version 2.15 or later.
 - You have installed the **freeipa.ansible_freeipa** collection.
 - The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.
 - The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin password**.
- The target node, that is the node on which the **freeipa.ansible_freeipa** module is executed, is part of the IdM domain as an IdM client, server or replica.
- You must have the name of the existing member manager user or group you are removing and the name of the group they are managing.

Procedure

1. Create an Ansible playbook file with the necessary user and group member management information:

- name: Playbook to handle membership management hosts: ipaserver

vars files:

- /home/user_name/MyPlaybooks/secret.yml

- name: Ensure member manager user and group members are absent for group_a freeipa.ansible_freeipa.ipagroup:

ipaadmin_password: "{{ ipaadmin_password }}"

name: group_a

membermanager user: test

membermanager_group: group_admins

action: member state: absent

2. Run the playbook:

\$ ansible-playbook --vault-password-file=password_file -v -i path_to_inventory_directory/inventory.file path_to_playbooks_directory/ensuremember-managers-are-absent.yml

Verification

You can verify if the **group_a** group does not contain **test** as a member manager and **group_admins** as a member manager of **group_a** by using the **ipa group-show** command:

1. Log into **ipaserver** as administrator:

\$ ssh admin@server.idm.example.com
Password:
[admin@server /]\$

2. Display information about group_a:

ipaserver]\$ ipa group-show group_a
Group name: group_a
GID: 1133400009

Additional resources

- See ipa host-remove-member-manager --help.
- See the **ipa** man page on your system.

CHAPTER 25. AUTOMATING GROUP MEMBERSHIP USING IDM CLI

Using automatic group membership allows you to assign users and hosts to groups automatically based on their attributes. For example, you can:

- Divide employees' user entries into groups based on the employees' manager, location, or any other attribute.
- Divide hosts based on their class, location, or any other attribute.
- Add all users or all hosts to a single global group.

25.1. BENEFITS OF AUTOMATIC GROUP MEMBERSHIP

Using automatic membership for users allows you to:

- Reduce the overhead of manually managing group memberships
 You no longer have to assign every user and host to groups manually.
- Improve consistency in user and host management
 Users and hosts are assigned to groups based on strictly defined and automatically evaluated criteria.
- Simplify the management of group-based settings

 Various settings are defined for groups and then applied to individual group members, for example **sudo** rules, automount, or access control. Adding users and hosts to groups automatically makes managing these settings easier.

25.2. AUTOMEMBER RULES

When configuring automatic group membership, the administrator defines automember rules. An automember rule applies to a specific user or host target group. It cannot apply to more than one group at a time.

After creating a rule, the administrator adds conditions to it. These specify which users or hosts get included or excluded from the target group:

- Inclusive conditions
 - When a user or host entry meets an inclusive condition, it will be included in the target group.
- Exclusive conditions

When a user or host entry meets an exclusive condition, it will not be included in the target group.

The conditions are specified as regular expressions in the Perl-compatible regular expressions (PCRE) format. For more information about PCRE, see the **pcresyntax(3)** man page on your system.

NOTE

IdM evaluates exclusive conditions before inclusive conditions. In case of a conflict, exclusive conditions take precedence over inclusive conditions.

An automember rule applies to every entry created in the future. These entries will be automatically added to the specified target group. If an entry meets the conditions specified in multiple automember rules, it will be added to all the corresponding groups.

Existing entries are **not** affected by the new rule. If you want to change existing entries, see the following sections:

- Applying automember rules to existing entries using IdM CLI .
- Applying automember rules to existing entries using IdM Web UI .

25.3. ADDING AN AUTOMEMBER RULE USING IDM CLI

Follow this procedure to add an automember rule using the IdM CLI. For information about automember rules, see Automember rules.

After adding an automember rule, you can add conditions to it using the procedure described in Adding a condition to an automember rule.

NOTE

Existing entries are **not** affected by the new rule. If you want to change existing entries, see Applying automember rules to existing entries using IdM CLI.

Prerequisites

- You must be logged in as the administrator. For details, see
- The target group of the new rule must exist in IdM.

Procedure

- 1. Enter the **ipa automember-add** command to add an automember rule.
- 2. When prompted, specify:
 - **Automember rule**. This is the target group name.
 - **Grouping Type**. This specifies whether the rule targets a user group or a host group. To target a user group, enter **group**. To target a host group, enter **hostgroup**.

For example, to add an automember rule for a user group named **user_group**:

\$ ipa automember-add
Automember Rule: user_group
Grouping Type: group
-----Added automember rule "user_group"
-----Automember Rule: user_group

Verification

• You can display existing automember rules and conditions in IdM using Viewing existing automember rules using IdM CLI.

25.4. ADDING A CONDITION TO AN AUTOMEMBER RULE USING IDM CLI

After configuring automember rules, you can then add a condition to that automember rule using the IdM CLI. For information about automember rules, see Automember rules.

Prerequisites

- You must be logged in as the administrator. For details, see Using kinit to log in to IdM manually.
- The target rule must exist in IdM. For details, see Adding an automember rule using IdM CLI.

Procedure

- 1. Define one or more inclusive or exclusive conditions using the **ipa automember-add-condition** command.
- 2. When prompted, specify:
 - Automember rule. This is the target rule name. See Automember rules for details.
 - Attribute Key. This specifies the entry attribute to which the filter will apply. For example, uid for users.
 - **Grouping Type**. This specifies whether the rule targets a user group or a host group. To target a user group, enter **group**. To target a host group, enter **hostgroup**.
 - Inclusive regex and Exclusive regex. These specify one or more conditions as regular expressions. If you only want to specify one condition, press Enter when prompted for the other.

For example, the following condition targets all users with any value (.*) in their user login attribute (uid).

As another example, you can use an automembership rule to target all Windows users synchronized from Active Directory (AD). To achieve this, create a condition that that targets all users with **ntUser** in their **objectClass** attribute, which is shared by all AD users:

\$ ipa automember-add-condition Automember Rule: ad_users Attribute Key: objectclass
Grouping Type: group
[Inclusive Regex]: ntUser
[Exclusive Regex]:
-----Added condition(s) to "ad_users"
-----Automember Rule: ad_users
Inclusive Regex: objectclass=ntUser
-----Number of conditions added 1

Verification

• You can display existing automember rules and conditions in IdM using Viewing existing automember rules using IdM CLI.

25.5. VIEWING EXISTING AUTOMEMBER RULES USING IDM CLI

Follow this procedure to view existing automember rules using the IdM CLI.

Prerequisites

• You must be logged in as the administrator. For details, see Using kinit to log in to IdM manually .

Procedure

- 1. Enter the **ipa automember-find** command.
- 2. When prompted, specify the Grouping type:
 - To target a user group, enter **group**.
 - To target a host group, enter hostgroup.
 For example:

```
$ ipa automember-find
Grouping Type: group
------

1 rules matched
------
Automember Rule: user_group
Inclusive Regex: uid=.*
-----
Number of entries returned 1
```

25.6. DELETING AN AUTOMEMBER RULE USING IDM CLI

Follow this procedure to delete an automember rule using the IdM CLI.

Deleting an automember rule also deletes all conditions associated with the rule. To remove only specific conditions from a rule, see Removing a condition from an automember rule using IdM CLI .

Prerequisites

• You must be logged in as the administrator. For details, see Using kinit to log in to IdM manually.

Procedure

- 1. Enter the ipa automember-del command.
- 2. When prompted, specify:
 - Automember rule. This is the rule you want to delete.
 - **Grouping rule**. This specifies whether the rule you want to delete is for a user group or a host group. Enter **group** or **hostgroup**.

25.7. REMOVING A CONDITION FROM AN AUTOMEMBER RULE USING IDM CLI

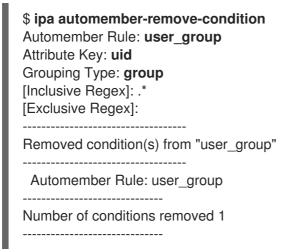

Follow this procedure to remove a specific condition from an automember rule.

Prerequisites

• You must be logged in as the administrator. For details, see Using kinit to log in to IdM manually .

Procedure

- 1. Enter the ipa automember-remove-condition command.
- 2. When prompted, specify:
 - Automember rule. This is the name of the rule from which you want to remove a condition.
 - Attribute Key. This is the target entry attribute. For example, uid for users.
 - **Grouping Type**. This specifies whether the condition you want to delete is for a user group or a host group. Enter **group** or **hostgroup**.
 - Inclusive regex and Exclusive regex. These specify the conditions you want to remove. If you only want to specify one condition, press Enter when prompted for the other.
 For example:

25.8. APPLYING AUTOMEMBER RULES TO EXISTING ENTRIES USING IDM CLI

Automember rules apply automatically to user and host entries created after the rules were added. They are not applied retroactively to entries that existed before the rules were added.

To apply automember rules to previously added entries, you have to manually rebuild automatic membership. Rebuilding automatic membership re-evaluates all existing automember rules and applies them either to all user or hosts entries, or to specific entries.

Rebuilding automatic membership **does not** remove user or host entries from groups, even if the entries no longer match the group's inclusive conditions. To remove them manually, see Removing a member from a user group using IdM CLI or Removing IdM host group members using the CLI.

Prerequisites

 You must be logged in as the administrator. For details, see link: Using kinit to log in to IdM manually.

Procedure

- To rebuild automatic membership, enter the **ipa automember-rebuild** command. Use the following options to specify the entries to target:
 - To rebuild automatic membership for all users, use the **--type=group** option:

- To rebuild automatic membership for all hosts, use the **--type=hostgroup** option.
- To rebuild automatic membership for a specified user or users, use the -users=target_user option:

 To rebuild automatic membership for a specified host or hosts, use the -hosts=client.idm.example.com option.

25.9. CONFIGURING A DEFAULT AUTOMEMBER GROUP USING IDM CLI

When you configure a default automember group, new user or host entries that do not match any automember rule are automatically added to this default group.

Prerequisites

You must be logged in as the administrator. For details, see Using kinit to log in to IdM manually.

• The target group you want to set as default exists in IdM.

Procedure

- 1. Enter the **ipa automember-default-group-set** command to configure a default automember group.
- 2. When prompted, specify:
 - **Default (fallback) Group**, which specifies the target group name.
 - Grouping Type, which specifies whether the target is a user group or a host group. To target a user group, enter group. To target a host group, enter hostgroup.
 For example:

```
$ ipa automember-default-group-set
Default (fallback) Group: default_user_group
Grouping Type: group
------
Set default (fallback) group for automember "default_user_group"
------
Default (fallback) Group:
cn=default_user_group,cn=groups,cn=accounts,dc=example,dc=com
```

NOTE

To remove the current default automember group, enter the **ipa automember-default-group-remove** command.

Verification

• To verify that the group is set correctly, enter the **ipa automember-default-group-show** command. The command displays the current default automember group. For example:

\$ ipa automember-default-group-show

Grouping Type: **group**Default (fallback) Group:
cn=default_user_group,cn=groups,cn=accounts,dc=example,dc=com

CHAPTER 26. AUTOMATING GROUP MEMBERSHIP USING IDM WEB UI

Using automatic group membership enables you to assign users and hosts to groups automatically based on their attributes. For example, you can:

- Divide employees' user entries into groups based on the employees' manager, location, or any other attribute.
- Divide hosts based on their class, location, or any other attribute.
- Add all users or all hosts to a single global group.

For details about benefits of automatic membership, see Benefits of automatic group membership section.

26.1. ADDING AN AUTOMEMBER RULE USING IDM WEB UI

Follow this procedure to add an automember rule using the IdM Web UI. For information about automember rules, see Automember rules.

Existing entries are **not** affected by the new rule. If you want to change existing entries, see Applying automember rules to existing entries using IdM Web UI.

Prerequisites

- You are logged in to the IdM Web UI.
- You must be a member of the **admins** group.
- The target group of the new rule exists in IdM.

Procedure

- 1. Click Identity → Automember, and select either User group rules or Host group rules.
- 2. Click Add.
- 3. In the **Automember rule** field, select the group to which the rule will apply. This is the target group name.
- 4. Click Add to confirm.
- 5. Optional: You can add conditions to the new rule using the procedure described in Adding a condition to an automember rule using IdM Web UI.

26.2. ADDING A CONDITION TO AN AUTOMEMBER RULE USING IDM WEB UI

After configuring automember rules, you can then add a condition to that automember rule using the IdM Web UI. For information about automember rules, see Automember rules.

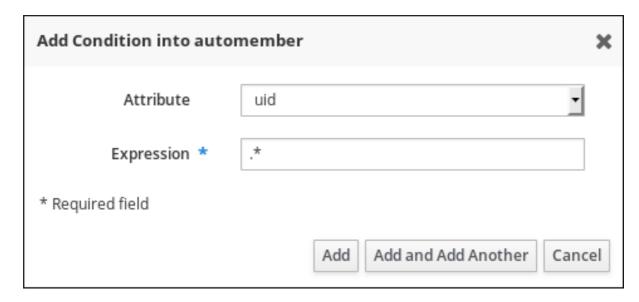

Prerequisites

- You are logged in to the IdM Web UI.
- You must be a member of the **admins** group.
- The target rule exists in IdM.

Procedure

- 1. Click Identity → Automember, and select either User group rules or Host group rules.
- 2. Click on the rule to which you want to add a condition.
- 3. In the Inclusive or Exclusive sections, click Add.
- 4. In the **Attribute** field, select the required attribute, for example *uid*.
- 5. In the **Expression** field, define a regular expression.
- 6. Click Add.

For example, the following condition targets all users with any value (.*) in their user ID (uid) attribute.

26.3. VIEWING EXISTING AUTOMEMBER RULES AND CONDITIONS USING IDM WEB UI

Follow this procedure to view existing automember rules and conditions using the IdM Web UI.

Prerequisites

- You are logged in to the IdM Web UI.
- You must be a member of the **admins** group.

Procedure

- Click Identity → Automember, and select either User group rules or Host group rules to view the respective automember rules.
- 2. Optional: Click on a rule to see the conditions for that rule in the **Inclusive** or **Exclusive** sections.

26.4. DELETING AN AUTOMEMBER RULE USING IDM WEB UI

Follow this procedure to delete an automember rule using the IdM Web UI.

Deleting an automember rule also deletes all conditions associated with the rule. To remove only specific conditions from a rule, see Removing a condition from an automember rule using IdM Web UI.

Prerequisites

- You are logged in to the IdM Web UI.
- You must be a member of the **admins** group.

Procedure

- Click Identity → Automember, and select either User group rules or Host group rules to view the respective automember rules.
- 2. Select the checkbox next to the rule you want to remove.
- 3. Click Delete.
- 4. Click **Delete** to confirm.

26.5. REMOVING A CONDITION FROM AN AUTOMEMBER RULE USING IDM WEB UI

Follow this procedure to remove a specific condition from an automember rule using the IdM Web UI.

Prerequisites

- You are logged in to the IdM Web UI.
- You must be a member of the **admins** group.

Procedure

- Click Identity → Automember, and select either User group rules or Host group rules to view the respective automember rules.
- 2. Click on a rule to see the conditions for that rule in the Inclusive or Exclusive sections.
- 3. Select the checkbox next to the conditions you want to remove.
- 4. Click Delete.
- 5. Click **Delete** to confirm.

26.6. APPLYING AUTOMEMBER RULES TO EXISTING ENTRIES USING IDM WEB UI

Automember rules apply automatically to user and host entries created after the rules were added. They are not applied retroactively to entries that existed before the rules were added.

To apply automember rules to previously added entries, you have to manually rebuild automatic membership. Rebuilding automatic membership re-evaluates all existing automember rules and applies them either to all user or hosts entries, or to specific entries.

Rebuilding automatic membership **does not** remove user or host entries from groups, even if the entries no longer match the group's inclusive conditions. To remove them manually, see the following sections:

- Removing a member from a user group using IdM Web UI
- Removing host group members in the IdM Web UI

26.6.1. Rebuilding automatic membership for all users or hosts

Follow this procedure to rebuild automatic membership for all user or host entries.

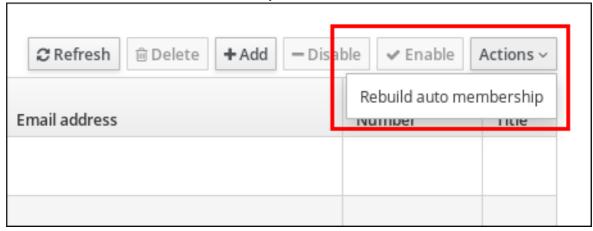

Prerequisites

- You are logged in to the IdM Web UI.
- You must be a member of the **admins** group.

Procedure

1. Select **Identity** → **Users** or **Hosts**.

2. Click Actions → Rebuild auto membership.

26.6.2. Rebuilding automatic membership for a single user or host only

Follow this procedure to rebuild automatic membership for a specific user or host entry.

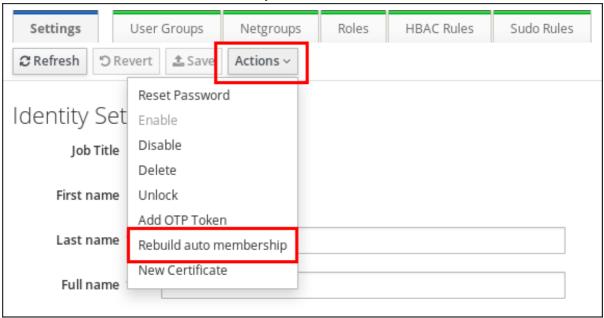

Prerequisites

- You are logged in to the IdM Web UI.
- You must be a member of the **admins** group.

Procedure

- 1. Select **Identity** → **Users** or **Hosts**.
- 2. Click on the required user or host name.

Click Actions → Rebuild auto membership.

26.7. CONFIGURING A DEFAULT USER GROUP USING IDM WEB UI

When you configure a default user group, new user entries that do not match any automember rule are automatically added to this default group.

Prerequisites

- You are logged in to the IdM Web UI.
- You must be a member of the **admins** group.
- The target user group you want to set as default exists in IdM.

Procedure

- 1. Click Identity → Automember, and select User group rules.
- 2. In the **Default user group** field, select the group you want to set as the default user group.

26.8. CONFIGURING A DEFAULT HOST GROUP USING IDM WEB UI

When you configure a default host group, new host entries that do not match any automember rule are automatically added to this default group.

Prerequisites

- You are logged in to the IdM Web UI.
- You must be a member of the **admins** group.
- The target host group you want to set as default exists in IdM.

Procedure

1. Click Identity → Automember, and select Host group rules.

2. In the Default host group field, select the group you want to set as the default host group.	

CHAPTER 27. USING ANSIBLE TO AUTOMATE GROUP MEMBERSHIP IN IDM

Using automatic group membership, you can assign users and hosts user groups and host groups automatically, based on their attributes. For example, you can:

- Divide employees' user entries into groups based on the employees' manager, location, position or any other attribute. You can list all attributes by entering **ipa user-add --help** on the command-line.
- Divide hosts into groups based on their class, location, or any other attribute. You can list all attributes by entering **ipa host-add --help** on the command-line.
- Add all users or all hosts to a single global group.

You can use Ansible to automate the management of automatic group membership in Identity Management (IdM).

27.1. USING ANSIBLE TO ENSURE THAT AN AUTOMEMBER RULE FOR AN IDM USER GROUP IS PRESENT

The following procedure describes how to use an Ansible playbook to ensure an **automember** rule for an Identity Management (IdM) group exists. In the example, the presence of an **automember** rule is ensured for the **testing_group** user group.

Prerequisites

- The **testing group** user group exists in IdM.
- You have configured your Ansible control node to meet the following requirements:
 - You are using Ansible version 2.15 or later.
 - You have installed the **freeipa.ansible freeipa** collection.
 - The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.
 - The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin_password** and that you have access to a file that stores the password protecting the **secret.yml** file.
- The target node, that is the node on which the freeipa.ansible_freeipa module is executed, is part of the IdM domain as an IdM client, server or replica.

Procedure

- 1. Navigate to your ~/MyPlaybooks/ directory:
 - \$ cd ~/MyPlaybooks/
- 2. Copy the **automember-group-present.yml** Ansible playbook file located in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/auto member/ directory:

\$ cp

/usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/a utomember-group-present.yml automember-group-present-copy.yml

- 3. Open the automember-group-present-copy.yml file for editing.
- 4. Adapt the file by setting the following variables in the **freeipa.ansible_freeipa.ipaautomember** task section:
 - Set the **ipaadmin password** variable to the password of the IdM **admin**.
 - Set the **name** variable to **testing_group**.
 - Set the automember_type variable to group.
 - Ensure that the **state** variable is set to **present**.

This is the modified Ansible playbook file for the current example:

- name: Automember group present example

hosts: ipaserver vars files:

- /home/user_name/MyPlaybooks/secret.yml

tasks:

- name: Ensure group automember rule admins is present

freeipa.ansible_freeipa.ipaautomember:

ipaadmin_password: "{{ ipaadmin_password }}"

name: testing_group automember_type: group

state: present

- 5. Save the file.
- 6. Run the Ansible playbook. Specify the playbook file, the file storing the password protecting the **secret.yml** file, and the inventory file:

\$ ansible-playbook --vault-password-file=password_file -v -i inventory automember-group-present-copy.yml

27.2. USING ANSIBLE TO ENSURE THAT A SPECIFIED CONDITION IS PRESENT IN AN IDM USER GROUP AUTOMEMBER RULE

The following procedure describes how to use an Ansible playbook to ensure that a specified condition exists in an **automember** rule for an Identity Management (IdM) group. In the example, the presence of a UID-related condition in the **automember** rule is ensured for the **testing_group** group. By specifying the .* condition, you ensure that all future IdM users automatically become members of the **testing_group**.

Prerequisites

- The **testing_group** user group and automember user group rule exist in IdM.
- You have configured your Ansible control node to meet the following requirements:

- You are using Ansible version 2.15 or later.
- You have installed the freeipa.ansible freeipa collection.
- The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.
- The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin_password** and that you have access to a file that stores the password protecting the **secret.yml** file.
- The target node, that is the node on which the **freeipa.ansible_freeipa** module is executed, is part of the IdM domain as an IdM client, server or replica.

Procedure

1. Navigate to your ~/MyPlaybooks/ directory:

\$ cd ~/MyPlaybooks/

 Copy the automember-hostgroup-rule-present.yml Ansible playbook file located in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/auto member/ directory and name it, for example, automember-usergroup-rule-present.yml:

\$ cp /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/a utomember/automember-hostgroup-rule-present.yml automember-usergroup-rulepresent.yml

- 3. Open the automember-usergroup-rule-present.yml file for editing.
- 4. Adapt the file by modifying the following parameters:
 - Rename the playbook to correspond to your use case, for example: Automember user group rule member present.
 - Rename the task to correspond to your use case, for example: Ensure an automember condition for a user group is present.
 - Set the following variables in the **freeipa.ansible_freeipa.ipaautomember** task section:
 - Set the **ipaadmin password** variable to the password of the IdM **admin**.
 - Set the **name** variable to **testing_group**.
 - Set the **automember_type** variable to **group**.
 - Ensure that the **state** variable is set to **present**.
 - Ensure that the **action** variable is set to **member**.
 - Set the **inclusive key** variable to **UID**.
 - Set the **inclusive expression** variable to .*

This is the modified Ansible playbook file for the current example:

--

- name: Automember user group rule member present

hosts: ipaserver vars files:

- /home/user_name/MyPlaybooks/secret.yml

tasks:

- name: Ensure an automember condition for a user group is present

freeipa.ansible_freeipa.ipaautomember:

ipaadmin_password: "{{ ipaadmin_password }}"

name: testing_group automember_type: group

state: present action: member

inclusive:
- key: UID
expression: .*

- 5. Save the file.
- 6. Run the Ansible playbook. Specify the playbook file, the file storing the password protecting the **secret.yml** file, and the inventory file:

\$ ansible-playbook --vault-password-file=password_file -v -i inventory automember-usergroup-rule-present.yml

Verification

1. Log in as an IdM administrator.

\$ kinit admin

2. Add a user, for example:

\$ ipa user-add user101 --first user --last 101

Added user "user101"

User login: user101 First name: user Last name: 101

...

Member of groups: ipausers, testing_group

...

27.3. USING ANSIBLE TO ENSURE THAT A CONDITION IS ABSENT FROM AN IDM USER GROUP AUTOMEMBER RULE

The following procedure describes how to use an Ansible playbook to ensure a condition is absent from an **automember** rule for an Identity Management (IdM) group. In the example, the absence of a condition in the **automember** rule is ensured that specifies that users whose **initials** are **dp** should be included. The automember rule is applied to the **testing_group** group. By applying the condition, you ensure that no future IdM user whose initials are **dp** becomes a member of the **testing_group**.

Prerequisites

- The **testing_group** user group and automember user group rule exist in IdM.
- You have configured your Ansible control node to meet the following requirements:
 - You are using Ansible version 2.15 or later.
 - You have installed the **freeipa.ansible_freeipa** collection.
 - The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.
 - The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin_password** and that you have access to a file that stores the password protecting the **secret.yml** file.
- The target node, that is the node on which the **freeipa.ansible_freeipa** module is executed, is part of the IdM domain as an IdM client, server or replica.

Procedure

1. Navigate to your ~/MyPlaybooks/ directory:

\$ cd ~/MyPlaybooks/

2. Copy the **automember-hostgroup-rule-absent.yml** Ansible playbook file located in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/auto member/ directory and name it, for example, automember-usergroup-rule-absent.yml:

\$ cp /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/a utomember/automember-hostgroup-rule-absent.yml automember-usergroup-rule-absent.yml

- 3. Open the **automember-usergroup-rule-absent.yml** file for editing.
- 4. Adapt the file by modifying the following parameters:
 - Rename the playbook to correspond to your use case, for example: Automember user group rule member absent.
 - Rename the task to correspond to your use case, for example: **Ensure an automember condition for a user group is absent**.
 - Set the following variables in the **freeipa.ansible_freeipa.ipaautomember** task section:
 - Set the **ipaadmin_password** variable to the password of the IdM **admin**.
 - Set the **name** variable to **testing group**.
 - Set the **automember_type** variable to **group**.
 - Ensure that the **state** variable is set to **absent**.
 - Ensure that the **action** variable is set to **member**.
 - Set the **inclusive key** variable to **initials**.

• Set the **inclusive expression** variable to **dp**.

This is the modified Ansible playbook file for the current example:

- name: Automember user group rule member absent

hosts: ipaserver vars files:

- /home/user_name/MyPlaybooks/secret.yml

tasks:

- name: Ensure an automember condition for a user group is absent

freeipa.ansible_freeipa.ipaautomember:

ipaadmin_password: "{{ ipaadmin_password }}"

name: testing_group automember_type: group

state: absent action: member inclusive: - key: initials expression: dp

5. Save the file.

6. Run the Ansible playbook. Specify the playbook file, the file storing the password protecting the **secret.yml** file, and the inventory file:

\$ ansible-playbook --vault-password-file=password_file -v -i inventory automember-usergroup-rule-absent.yml

Verification

1. Log in as an IdM administrator.

\$ kinit admin

2. View the automember group:

\$ ipa automember-show --type=group testing_group
Automember Rule: testing_group

The absence of an **Inclusive Regex: initials=dp** entry in the output confirms that the **testing_group** automember rule does not contain the condition specified.

27.4. USING ANSIBLE TO ENSURE THAT AN AUTOMEMBER RULE FOR AN IDM USER GROUP IS ABSENT

The following procedure describes how to use an Ansible playbook to ensure an **automember** rule is absent for an Identity Management (IdM) group. In the example, the absence of an **automember** rule is ensured for the **testing_group** group.

NOTE

Deleting an automember rule also deletes all conditions associated with the rule. To remove only specific conditions from a rule, see Using Ansible to ensure that a condition is absent in an IdM user group automember rule.

Prerequisites

- On the control node:
 - You are using Ansible version 2.15 or later.
 - You have installed the **freeipa.ansible_freeipa** collection.
 - The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.
 - The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin_password** and that you have access to a file that stores the password protecting the **secret.yml** file.
- The target node, that is the node on which the **freeipa.ansible_freeipa** module is executed, is part of the IdM domain as an IdM client, server or replica.

Procedure

1. Navigate to your ~/MyPlaybooks/ directory:

\$ cd ~/MyPlaybooks/

 Copy the automember-group-absent.yml Ansible playbook file located in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/auto member/ directory:

\$ cp

/usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/a utomember-group-absent.yml automember-group-absent-copy.yml

- 3. Open the automember-group-absent-copy.yml file for editing.
- 4. Adapt the file by setting the following variables in the **freeipa.ansible_freeipa.ipaautomember** task section:
 - Set the **ipaadmin_password** variable to the password of the IdM **admin**.
 - Set the **name** variable to **testing_group**.
 - Set the **automember_type** variable to **group**.
 - Ensure that the **state** variable is set to **absent**.
 This is the modified Ansible playbook file for the current example:

- name: Automember group absent example

hosts: ipaserver vars_files:

- /home/user name/MyPlaybooks/secret.yml

tasks:

- name: Ensure group automember rule admins is absent

freeipa.ansible freeipa.ipaautomember:

ipaadmin password: "{{ ipaadmin password }}"

name: testing_group automember_type: group

state: absent

5. Save the file.

6. Run the Ansible playbook. Specify the playbook file, the file storing the password protecting the **secret.yml** file, and the inventory file:

\$ ansible-playbook --vault-password-file=password_file -v -i inventory automember-group-absent.yml

Additional resources

- See the **README-automember.md** file in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/ directory.
- See the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/auto member directory.

27.5. USING ANSIBLE TO ENSURE THAT A CONDITION IS PRESENT IN AN IDM HOST GROUP AUTOMEMBER RULE

Follow this procedure to use Ansible to ensure that a condition is present in an IdM host group automember rule. The example describes how to ensure that hosts with the **FQDN** of .*.idm.example.com are members of the **primary_dns_domain_hosts** host group and hosts whose **FQDN** is .*.example.org are not members of the **primary_dns_domain_hosts** host group.

Prerequisites

- The primary dns domain hosts host group and automember host group rule exist in IdM.
- You have configured your Ansible control node to meet the following requirements:
 - You are using Ansible version 2.15 or later.
 - You have installed the **freeipa.ansible freeipa** collection.
 - The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.
 - The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin_password** and that you have access to a file that stores the password protecting the **secret.yml** file.
- The target node, that is the node on which the **freeipa.ansible_freeipa** module is executed, is part of the IdM domain as an IdM client, server or replica.

Procedure

1. Navigate to your ~/MyPlaybooks/ directory:

\$ cd ~/MyPlaybooks/

 Copy the automember-hostgroup-rule-present.yml Ansible playbook file located in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/auto member/ directory:

\$ cp

/usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/a utomember/automember-hostgroup-rule-present.yml automember-hostgroup-rule-present-copy.yml

- 3. Open the automember-hostgroup-rule-present-copy.yml file for editing.
- 4. Adapt the file by setting the following variables in the **freeipa.ansible_freeipa.ipaautomember** task section:
 - Set the **ipaadmin_password** variable to the password of the IdM **admin**.
 - Set the **name** variable to **primary_dns_domain_hosts**.
 - Set the **automember_type** variable to **hostgroup**.
 - Ensure that the **state** variable is set to **present**.
 - Ensure that the action variable is set to member.
 - Ensure that the **inclusive key** variable is set to **fqdn**.
 - Set the corresponding inclusive expression variable to .*.idm.example.com.
 - Set the **exclusive key** variable to **fqdn**.
 - Set the corresponding exclusive expression variable to .*.example.org.

This is the modified Ansible playbook file for the current example:

- name: Automember user group rule member present

hosts: ipaserver vars files:

- /home/user_name/MyPlaybooks/secret.yml

tasks

- name: Ensure an automember condition for a user group is present freeipa.ansible freeipa.ipaautomember:

ipaadmin_password: "{{ ipaadmin_password }}"

name: primary_dns_domain_hosts automember_type: hostgroup

state: present action: member inclusive:

- key: fqdn

expression: .*.idm.example.com

exclusive: - key: fqdn

expression: .*.example.org

- 5. Save the file.
- 6. Run the Ansible playbook. Specify the playbook file, the file storing the password protecting the **secret.yml** file, and the inventory file:

\$ ansible-playbook --vault-password-file=password_file -v -i inventory automember-hostgroup-rule-present-copy.yml

Additional resources

- /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/READMEautomember.md
- /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/auto member

CHAPTER 28. DELEGATING PERMISSIONS TO USER GROUPS TO MANAGE USERS USING IDM CLI

Delegation is one of the access control methods in IdM, along with self-service rules and role-based access control (RBAC). You can use delegation to assign permissions to one group of users to manage entries for another group of users.

28.1. DELEGATION RULES

You can delegate permissions to user groups to manage users by creating delegation rules.

Delegation rules allow a specific user group to perform write (edit) operations on specific attributes for users in another user group. This form of access control rule is limited to editing the values of a subset of attributes you specify in a delegation rule; it does not grant the ability to add or remove whole entries or control over unspecified attributes.

Delegation rules grant permissions to existing user groups in IdM. You can use delegation to, for example, allow the **managers** user group to manage selected attributes of users in the **employees** user group.

28.2. CREATING A DELEGATION RULE USING IDM CLI

Follow this procedure to create a delegation rule using the IdM CLI.

Prerequisites

• You are logged in as a member of the **admins** group.

Procedure

- Enter the **ipa delegation-add** command. Specify the following options:
 - **--group**: the group who *is being granted permissions* to the entries of users in the user group.
 - **--membergroup**: the group *whose entries can be edited* by members of the delegation group.
 - **--permissions**: whether users will have the right to view the given attributes (*read*) and add or change the given attributes (*write*). If you do not specify permissions, only the *write* permission will be added.
 - --attrs: the attributes which users in the member group are allowed to view or edit.

For example:

\$ ipa delegation-add "basic manager attributes" --permissions=read --permissions=write -attrs=businesscategory --attrs=departmentnumber --attrs=employeetype -attrs=employeenumber --group=managers --membergroup=employees

Added delegation "basic manager attributes"

Delegation name: basic manager attributes

Permissions: read, write

Attributes: businesscategory, departmentnumber, employeetype, employeenumber

Member user group: employees

User group: managers

28.3. VIEWING EXISTING DELEGATION RULES USING IDM CLI

Follow this procedure to view existing delegation rules using the IdM CLI.

Prerequisites

• You are logged in as a member of the **admins** group.

Procedure

• Enter the **ipa delegation-find** command:

\$ ipa delegation-find

1 delegation matched

Delegation name: basic manager attributes

Permissions: read, write

Attributes: businesscategory, departmentnumber, employeenumber, employeetype

Member user group: employees

User group: managers

Number of entries returned 1

28.4. MODIFYING A DELEGATION RULE USING IDM CLI

Follow this procedure to modify an existing delegation rule using the IdM CLI.

IMPORTANT

The **--attrs** option overwrites whatever the previous list of supported attributes was, so always include the complete list of attributes along with any new attributes. This also applies to the **--permissions** option.

Prerequisites

• You are logged in as a member of the **admins** group.

Procedure

• Enter the **ipa delegation-mod** command with the desired changes. For example, to add the **displayname** attribute to the **basic manager attributes** example rule:

\$ ipa delegation-mod "basic manager attributes" --attrs=businesscategory --attrs=departmentnumber --attrs=employeetype --attrs=employeenumber --attrs=displayname

Modified delegation "basic manager attributes"

Delegation name: basic manager attributes

Permissions: read, write

Attributes: businesscategory, departmentnumber, employeetype, employeenumber,

displayname

Member user group: employees

User group: managers

28.5. DELETING A DELEGATION RULE USING IDM CLI

Follow this procedure to delete an existing delegation rule using the IdM CLI.

Prerequisites

• You are logged in as a member of the **admins** group.

Procedure

- Enter the **ipa delegation-del** command.
- When prompted, enter the name of the delegation rule you want to delete:

\$ ipa delegation-del
Delegation name: basic manager attributes
----Deleted delegation "basic manager attributes"

CHAPTER 29. DELEGATING PERMISSIONS TO USER GROUPS TO MANAGE USERS USING IDM WEBUI

Delegation is one of the access control methods in IdM, along with self-service rules and role-based access control (RBAC). You can use delegation to assign permissions to one group of users to manage entries for another group of users.

For details about delegation rules general information, see Delegation rules section.

29.1. CREATING A DELEGATION RULE USING IDM WEBUI

Follow this procedure to create a delegation rule using the IdM WebUI.

Prerequisites

• You are logged in to the IdM Web UI as a member of the **admins** group.

Procedure

- 1. From the IPA Server>Role-Based Access Control menu, click Delegations.
- 2. Click Add.
- 3. On the Add delegation window, do the following:
 - a. Name the new delegation rule.
 - b. Set the permissions by selecting the checkboxes that indicate whether users will have the right to view the given attributes (*read*) and add or change the given attributes (*write*).
 - c. From the **User group** drop-down menu, select the group *who is being granted permissions* to view or edit the entries of users in the member group.
 - d. On the **Member user group** drop-down menu, select the group *whose entries can be edited* by members of the delegation group.
 - e. In the attributes box, select the checkboxes by the attributes to which you want to grant permissions.
 - f. Click the **Add** button to save the new delegation rule.

29.2. VIEWING EXISTING DELEGATION RULES USING IDM WEBUI

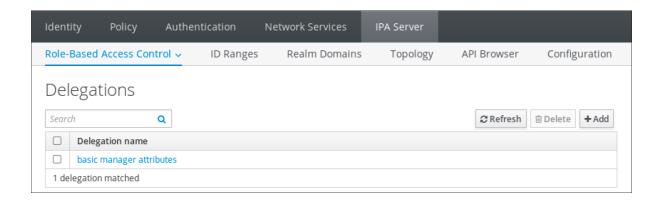

Follow this procedure to view existing delegation rules using the IdM WebUI.

Prerequisites

• You are logged in to the IdM Web UI as a member of the **admins** group.

Procedure

• From the IPA Server>Role-Based Access Control menu, click Delegations.

29.3. MODIFYING A DELEGATION RULE USING IDM WEBUI

Follow this procedure to modify an existing delegation rule using the IdM WebUI.

Prerequisites

• You are logged in to the IdM Web UI as a member of the **admins** group.

Procedure

- 1. From the IPA Server>Role-Based Access Control menu, click Delegations.
- 2. Click the rule you want to modify.
- 3. Make the desired changes:
 - Change the name of the rule.
 - Change granted permissions by selecting the checkboxes that indicate whether users will
 have the right to view the given attributes (read) and add or change the given attributes
 (write).
 - In the User group drop-down menu, select the group who is being granted permissions to view or edit the entries of users in the member group.
 - In the **Member user group** drop-down menu, select the group *whose entries can be edited* by members of the delegation group.
 - In the attributes box, select the checkboxes by the attributes to which you want to grant permissions. To remove permissions to an attribute, uncheck the relevant checkbox.
 - Click the Save button to save the changes.

29.4. DELETING A DELEGATION RULE USING IDM WEBUI

Follow this procedure to delete an existing delegation rule using the IdM WebUI.

Prerequisites

• You are logged in to the IdM Web UI as a member of the **admins** group.

Procedure

1. From the IPA Server>Role-Based Access Control menu, click Delegations.

- 2. Select the checkbox next to the rule you want to remove.
- 3. Click **Delete**.
- 4. Click **Delete** to confirm.

CHAPTER 30. DELEGATING PERMISSIONS TO USER GROUPS TO MANAGE USERS USING ANSIBLE PLAYBOOKS

Delegation is one of the access control methods in IdM, along with self-service rules and role-based access control (RBAC). You can use delegation to assign permissions to one group of users to manage entries for another group of users.

For details about delegation rules general information, see Delegation rules section.

30.1. USING ANSIBLE TO ENSURE THAT A DELEGATION RULE IS PRESENT

The following procedure describes how to use an Ansible playbook to define privileges for a new IdM delegation rule and ensure its presence. In the example, the new **basic manager attributes** delegation rule grants the **managers** group the ability to read and write the following attributes for members of the **employees** group:

- businesscategory
- departmentnumber
- employeenumber
- employeetype

Prerequisites

- On the control node:
 - You are using Ansible version 2.15 or later.
 - You have installed the **freeipa.ansible_freeipa** collection.
 - The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.
 - The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin_password** and that you have access to a file that stores the password protecting the **secret.yml** file.
- The target node, that is the node on which the **freeipa.ansible_freeipa** module is executed, is part of the IdM domain as an IdM client, server or replica.

Procedure

1. Navigate to the ~/MyPlaybooks/ directory:

\$ cd ~/MyPlaybooks/

 Make a copy of the delegation-present.yml file located in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/dele gation/ directory: \$ cp

/usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/d elegation-present.yml delegation-present-copy.yml

- 3. Open the **delegation-present-copy.yml** Ansible playbook file for editing.
- 4. Adapt the file by setting the following variables in the **freeipa.ansible_freeipa.ipadelegation** task section:
 - Set the **name** variable to the name of the new delegation rule.
 - Set the **permission** variable to a comma-separated list of permissions to grant: **read** and write.
 - Set the **attribute** variable to a list of attributes the delegated user group can manage: **businesscategory**, **departmentnumber**, **employeenumber**, and **employeetype**.
 - Set the **group** variable to the name of the group that is being given access to view or modify attributes.
 - Set the membergroup variable to the name of the group whose attributes can be viewed or modified.

This is the modified Ansible playbook file for the current example:

- name: Playbook to manage a delegation rule

hosts: ipaserver

vars files:

- /home/user_name/MyPlaybooks/secret.yml

tasks:

- name: Ensure delegation "basic manager attributes" is present

freeipa.ansible_freeipa.ipadelegation:

ipaadmin password: "{{ ipaadmin password }}"

name: "basic manager attributes"

permission: read, write

attribute:

- businesscategory
- departmentnumber
- employeenumber
- employeetype

group: managers

membergroup: employees

- 5. Save the file.
- 6. Run the Ansible playbook. Specify the playbook file, the file storing the password protecting the **secret.yml** file, and the inventory file:

\$ ansible-playbook --vault-password-file=password_file -v -i ~/MyPlaybooks/inventory delegation-present-copy.yml

Additional resources

- Delegation rules
- The **README-delegation.md** file in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/ directory
- Sample playbooks in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/ipad elegation directory

30.2. USING ANSIBLE TO ENSURE THAT A DELEGATION RULE IS ABSENT

The following procedure describes how to use an Ansible playbook to ensure a specified delegation rule is absent from your IdM configuration. The example below describes how to make sure the custom **basic** manager attributes delegation rule does not exist in IdM.

Prerequisites

- On the control node:
 - You are using Ansible version 2.15 or later.
 - You have installed the freeipa.ansible_freeipa collection.
 - The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.
 - The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin_password** and that you have access to a file that stores the password protecting the **secret.yml** file.
- The target node, that is the node on which the **freeipa.ansible_freeipa** module is executed, is part of the IdM domain as an IdM client, server or replica.

Procedure

1. Navigate to the ~/MyPlaybooks/ directory:

\$ cd ~/MyPlaybooks>/

 Make a copy of the delegation-absent.yml file located in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/dele gation/ directory:

\$ cp

/usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/d elegation-present.yml delegation-absent-copy.yml

- 3. Open the **delegation-absent-copy.yml** Ansible playbook file for editing.
- 4. Adapt the file by setting the following variables in the **freeipa.ansible_freeipa.ipadelegation** task section:
 - Set the **name** variable to the name of the delegation rule.
 - Set the state variable to absent.

This is the modified Ansible playbook file for the current example:

- name: Delegation absent

hosts: ipaserver

vars files:

- /home/user_name/MyPlaybooks/secret.yml

tasks:

- name: Ensure delegation "basic manager attributes" is absent

freeipa.ansible_freeipa.ipadelegation:

ipaadmin_password: "{{ ipaadmin_password }}"

name: "basic manager attributes"

state: absent

5. Save the file.

6. Run the Ansible playbook. Specify the playbook file, the file storing the password protecting the **secret.yml** file, and the inventory file:

\$ ansible-playbook --vault-password-file=password_file -v -i ~/MyPlaybooks/inventory delegation-absent-copy.yml

Additional resources

- Delegation rules
- The README-delegation.md file in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/ directory
- Sample playbooks in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/ipad elegation directory

30.3. USING ANSIBLE TO ENSURE THAT A DELEGATION RULE HAS SPECIFIC ATTRIBUTES

The following procedure describes how to use an Ansible playbook to ensure that a delegation rule has specific settings. You can use this playbook to modify a delegation role you have previously created. In the example, you ensure the **basic manager attributes** delegation rule only has the **departmentnumber** member attribute.

Prerequisites

- On the control node:
 - You are using Ansible version 2.15 or later.
 - You have installed the **freeipa.ansible freeipa** collection.
 - The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.

- The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin_password** and that you have access to a file that stores the password protecting the **secret.yml** file.
- The target node, that is the node on which the **freeipa.ansible_freeipa** module is executed, is part of the IdM domain as an IdM client, server or replica.
- The basic manager attributes delegation rule exists in IdM.

Procedure

1. Navigate to the ~/MyPlaybooks/ directory:

\$ cd ~/MyPlaybooks/

 Make a copy of the delegation-member-present.yml file located in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/dele gation/ directory:

\$ cp

/usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/d elegation/delegation-member-present.yml delegation-member-present-copy.yml

- 3. Open the **delegation-member-present-copy.yml** Ansible playbook file for editing.
- 4. Adapt the file by setting the following variables in the **freeipa.ansible_freeipa.ipadelegation** task section:
 - Set the **name** variable to the name of the delegation rule to modify.
 - Set the attribute variable to departmentnumber.
 - Set the action variable to member.

This is the modified Ansible playbook file for the current example:

- name: Delegation member present

hosts: ipaserver

vars files:

- /home/user_name/MyPlaybooks/secret.yml

tasks:

- name: Ensure delegation "basic manager attributes" member attribute departmentnumber is present

freeipa.ansible_freeipa.ipadelegation:

ipaadmin_password: "{{ ipaadmin_password }}"

name: "basic manager attributes"

attribute:

- departmentnumber action: member

- 5. Save the file.
- 6. Run the Ansible playbook. Specify the playbook file, the file storing the password protecting the **secret.yml** file, and the inventory file:

-

\$ ansible-playbook --vault-password-file=password_file -v -i ~/MyPlaybooks/inventory delegation-member-present-copy.yml

Additional resources

- Delegation rules
- The README-delegation.md file in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/ directory
- The sample playbooks in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/ipad elegation directory

30.4. USING ANSIBLE TO ENSURE THAT A DELEGATION RULE DOES NOT HAVE SPECIFIC ATTRIBUTES

The following procedure describes how to use an Ansible playbook to ensure that a delegation rule does not have specific settings. You can use this playbook to make sure a delegation role does not grant undesired access. In the example, you ensure the **basic manager attributes** delegation rule does not have the **employeenumber** and **employeetype** member attributes.

Prerequisites

- On the control node:
 - You are using Ansible version 2.15 or later.
 - You have installed the **freeipa.ansible freeipa** collection.
 - The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.
 - The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin_password** and that you have access to a file that stores the password protecting the **secret.yml** file.
- The target node, that is the node on which the **freeipa.ansible_freeipa** module is executed, is part of the IdM domain as an IdM client, server or replica.
- The basic manager attributes delegation rule exists in IdM.

Procedure

1. Navigate to the ~/MyPlaybooks/ directory:

\$ cd ~/MyPlaybooks/

 Make a copy of the delegation-member-absent.yml file located in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/dele gation/ directory:

\$ cp

/usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/d elegation/delegation-member-absent.yml delegation-member-absent-copy.yml

- 3. Open the **delegation-member-absent-copy.yml** Ansible playbook file for editing.
- 4. Adapt the file by setting the following variables in the **freeipa.ansible_freeipa.ipadelegation** task section:
 - Set the **name** variable to the name of the delegation rule to modify.
 - Set the attribute variable to employeenumber and employeetype.
 - Set the action variable to member.
 - Set the state variable to absent.

This is the modified Ansible playbook file for the current example:

- name: Delegation member absent

hosts: ipaserver

vars files:

- /home/user_name/MyPlaybooks/secret.yml

tasks:

- name: Ensure delegation "basic manager attributes" member attributes employeenumber and employeetype are absent

freeipa.ansible_freeipa.ipadelegation:

ipaadmin_password: "{{ ipaadmin_password }}"

name: "basic manager attributes"

attribute:

- employeenumber
- employeetype action: member state: absent
- 5. Save the file.
- 6. Run the Ansible playbook. Specify the playbook file, the file storing the password protecting the **secret.yml** file, and the inventory file:

\$ ansible-playbook --vault-password-file=password_file -v -i ~/MyPlaybooks/inventory delegation-member-absent-copy.yml

Additional resources

- Delegation rules
- The **README-delegation.md** file in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/ directory.
- Sample playbooks in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/ipad elegation directory

CHAPTER 31. MANAGING ROLE-BASED ACCESS CONTROLS IN IDM USING THE CLI

Learn more about role-based access control (RBAC) in Identity Management (IdM). RBAC is a security feature that restricts access to authorized users. You can define roles with specific permissions and then assign those roles to users.

31.1. ROLE-BASED ACCESS CONTROL IN IDM

Role-based access control (RBAC) in IdM grants a very different kind of authority to users compared to self-service and delegation access controls.

Role-based access control is composed of three parts:

- Permissions grant the right to perform a specific task such as adding or deleting users, modifying a group, and enabling read-access.
- Privileges combine permissions, for example all the permissions needed to add a new user.
- Roles grant a set of privileges to users, user groups, hosts or host groups.

31.1.1. Permissions in IdM

Permissions are the lowest level unit of role-based access control, they define operations together with the LDAP entries to which those operations apply. Comparable to building blocks, permissions can be assigned to as many privileges as needed.

One or more rights define what operations are allowed:

- write
- read
- search
- compare
- add
- delete
- all

These operations apply to three basic targets:

- **subtree**: a domain name (DN); the subtree under this DN
- target filter: an LDAP filter
- target: DN with possible wildcards to specify entries

Additionally, the following convenience options set the corresponding attribute(s):

- type: a type of object (user, group, etc); sets subtree and target filter
- memberof: members of a group; sets a target filter

NOTE

Setting the **memberof** attribute permission is not applied if the target LDAP entry does not contain any reference to group membership.

• **targetgroup**: grants access to modify a specific group (such as granting the rights to manage group membership); sets a **target**

With IdM permissions, you can control which users have access to which objects and even which attributes of these objects. IdM enables you to allow or block individual attributes or change the entire visibility of a specific IdM function, such as users, groups, or sudo, to all anonymous users, all authenticated users, or just a certain group of privileged users.

For example, the flexibility of this approach to permissions is useful for an administrator who wants to limit access of users or groups only to the specific sections these users or groups need to access and to make the other sections completely hidden to them.

NOTE

A permission cannot contain other permissions.

31.1.2. Default managed permissions

Managed permissions are permissions that come by default with IdM. They behave like other permissions created by the user, with the following differences:

- You cannot delete them or modify their name, location, and target attributes.
- They have three sets of attributes:
 - Default attributes, the user cannot modify them, as they are managed by IdM
 - Included attributes, which are additional attributes added by the user
 - Excluded attributes, which are attributes removed by the user

A managed permission applies to all attributes that appear in the default and included attribute sets but not in the excluded set.

NOTE

While you cannot delete a managed permission, setting its bind type to permission and removing the managed permission from all privileges effectively disables it.

Names of all managed permissions start with **System:**, for example **System: Add Sudo rule** or **System: Modify Services**. Earlier versions of IdM used a different scheme for default permissions. For example, the user could not delete them and was only able to assign them to privileges. Most of these default permissions have been turned into managed permissions, however, the following permissions still use the previous scheme:

- Add Automember Rebuild Membership Task
- Add Configuration Sub-Entries
- Add Replication Agreements

- Certificate Remove Hold
- Get Certificates status from the CA
- Read DNA Range
- Modify DNA Range
- Read PassSync Managers Configuration
- Modify PassSync Managers Configuration
- Read Replication Agreements
- Modify Replication Agreements
- Remove Replication Agreements
- Read LDBM Database Configuration
- Request Certificate
- Request Certificate ignoring CA ACLs
- Request Certificates from a different host
- Retrieve Certificates from the CA
- Revoke Certificate
- Write IPA Configuration

NOTE

If you attempt to modify a managed permission from the command line, the system does not allow you to change the attributes that you cannot modify, the command fails. If you attempt to modify a managed permission from the Web UI, the attributes that you cannot modify are disabled.

31.1.3. Privileges in IdM

A privilege is a group of permissions applicable to a role.

While a permission provides the rights to do a single operation, there are certain IdM tasks that require multiple permissions to succeed. Therefore, a privilege combines the different permissions required to perform a specific task.

For example, setting up an account for a new IdM user requires the following permissions:

- Creating a new user entry
- Resetting a user password
- Adding the new user to the default IPA users group

Combining these three low-level tasks into a higher level task in the form of a custom privilege named, for example, **Add User** makes it easier for a system administrator to manage roles. IdM already contains several default privileges. Apart from users and user groups, privileges are also assigned to hosts and

host groups, as well as network services. This practice permits a fine-grained control of operations by a set of users on a set of hosts using specific network services.

NOTE

A privilege may not contain other privileges.

31.1.4. Roles in IdM

A role is a list of privileges that users specified for the role possess.

In effect, permissions grant the ability to perform given low-level tasks (such as creating a user entry and adding an entry to a group), privileges combine one or more of these permissions needed for a higher-level task (such as creating a new user in a given group). Roles gather privileges together as needed: for example, a User Administrator role would be able to add, modify, and delete users.

IMPORTANT

Roles are used to classify permitted actions. They are not used as a tool to implement privilege separation or to protect from privilege escalation.

NOTE

Roles can not contain other roles.

31.1.5. Predefined roles in Identity Management

Red Hat Enterprise Linux Identity Management provides the following range of pre-defined roles:

Table 31.1. Predefined Roles in Identity Management

Role	Privilege	Description
Enrollment Administrator	Host Enrollment	Responsible for client, or host, enrollment
helpdesk	Modify Users and Reset passwords, Modify Group membership	Responsible for performing simple user administration tasks
IT Security Specialist	Netgroups Administrators, HBAC Administrator, Sudo Administrator	Responsible for managing security policy such as host-based access controls, sudo rules
IT Specialist	Host Administrators, Host Group Administrators, Service Administrators, Automount Administrators	Responsible for managing hosts
Security Architect	Delegation Administrator, Replication Administrators, Write IPA Configuration, Password Policy Administrator	Responsible for managing the Identity Management environment, creating trusts, creating replication agreements

Role	Privilege	Description
User Administrator	User Administrators, Group Administrators, Stage User Administrators	Responsible for creating users and groups

31.2. MANAGING IDM PERMISSIONS IN THE CLI

Follow this procedure to manage Identity Management (IdM) permissions using the command line (CLI).

Prerequisites

- Administrator privileges for managing IdM or the **User Administrator** role.
- An active Kerberos ticket. For details, see Using kinit to log in to IdM manually.

Procedure

- Create new permission entries with the ipa permission-add command. For example, to add a permission named dns admin:
 - \$ ipa permission-add "dns admin"
- 2. Specify the properties of the permission with the following options:
 - --bindtype specifies the bind rule type. This option accepts the all, anonymous, and permission arguments. The permission bindtype means that only the users who are granted this permission via a role can exercise it.
 For example:
 - \$ ipa permission-add "dns admin" --bindtype=all

If you do not specify **--bindtype**, then **permission** is the default value.

NOTE

It is not possible to add permissions with a non-default bind rule type to privileges. You also cannot set a permission that is already present in a privilege to a non-default bind rule type.

- --right lists the rights granted by the permission, it replaces the deprecated --permissions option. The available values are add, delete, read, search, compare, write, all.
 You can set multiple attributes by using multiple --right options or with a comma-separated list inside curly braces. For example:
 - \$ ipa permission-add "dns admin" --right=read --right=write
 \$ ipa permission-add "dns admin" --right={read,write}

NOTE

add and **delete** are entry-level operations (for example, deleting a user, adding a group, and so on) while **read**, **search**, **compare** and **write** are more attribute-level: you can write to **userCertificate** but not read **userPassword**.

--attrs gives the list of attributes over which the permission is granted.
 You can set multiple attributes by using multiple --attrs options or by listing the options in a comma-separated list inside curly braces. For example:

\$ ipa permission-add "dns admin" --attrs=description --attrs=automountKey \$ ipa permission-add "dns admin" --attrs={description,automountKey}

The attributes provided with **--attrs** must exist and be allowed attributes for the given object type, otherwise the command fails with schema syntax errors.

 --type defines the entry object type to which the permission applies, such as user, host, or service. Each type has its own set of allowed attributes.
 For example:

\$ ipa permission-add "manage service" --right=all --type=service --attrs=krbprincipalkey --attrs=krbprincipalname --attrs=managedby

--subtree gives a subtree entry; the filter then targets every entry beneath this subtree entry. Provide an existing subtree entry; --subtree does not accept wildcards or non-existent domain names (DNs). Include a DN within the directory.
 Because IdM uses a simplified, flat directory tree structure, --subtree can be used to target some types of entries, like automount locations, which are containers or parent entries for other configuration. For example:

\$ ipa permission-add "manage automount locations" -- subtree="Idap://Idap.example.com:389/cn=automount,dc=example,dc=com" -- right=write --attrs=automountmapname --attrs=automountkey -- attrs=automountInformation

NOTE

The **--type** and **--subtree** options are mutually exclusive: you can see the inclusion of filters for **--type** as a simplification of **--subtree**, intending to make life easier for an admin.

--filter uses an LDAP filter to identify which entries the permission applies to.
 IdM automatically checks the validity of the given filter. The filter can be any valid LDAP filter, for example:

\$ ipa permission-add "manage Windows groups" --filter="(! (objectclass=posixgroup))" --right=write --attrs=description

 --memberof sets the target filter to members of the given group after checking that the group exists. For example, to let the users with this permission modify the login shell of members of the engineers group: \$ ipa permission-add ManageShell --right="write" --type=user --attr=loginshell --memberof=engineers

NOTE

Setting the **memberof** attribute permission is not applied if the target LDAP entry does not contain any reference to group membership.

• **--targetgroup** sets target to the specified user group after checking that the group exists. For example, to let those with the permission write the member attribute in the engineers group (so they can add or remove members):

\$ ipa permission-add ManageMembers --right="write" -subtree=cn=groups,cn=accounts,dc=example,dc=test --attr=member -targetgroup=engineers

- Optionally, you can specify a target domain name (DN):
 - --target specifies the DN to apply the permission to. Wildcards are accepted.
 - --targetto specifies the DN subtree where an entry can be moved to.
 - --targetfrom specifies the DN subtree from where an entry can be moved.

31.3. COMMAND OPTIONS FOR EXISTING PERMISSIONS

Use the following variants to modify existing permissions as needed:

- To edit existing permissions, use the **ipa permission-mod** command. You can use the same command options as for adding permissions.
- To find existing permissions, use the **ipa permission-find** command. You can use the same command options as for adding permissions.
- To view a specific permission, use the **ipa permission-show** command.

 The **--raw** argument shows the raw 389-ds ACI that is generated. For example:
 - \$ ipa permission-show <permission> --raw
- The **ipa permission-del** command deletes a permission completely.

Additional resources

- See the **ipa** man page on your system.
- See the **ipa help** command.

31.4. MANAGING IDM PRIVILEGES IN THE CLI

Follow this procedure to manage Identity Management (IdM) privileges using the command line (CLI).

Prerequisites

- Administrator privileges for managing IdM or the **User Administrator** role.
- An active Kerberos ticket. For details, see Using kinit to log in to IdM manually .
- Existing permissions. For details about permissions, see Managing IdM permissions in the CLI.

Procedure

- 1. Add privilege entries using the **ipa privilege-add** command For example, to add a privilege named *managing filesystems* with a description:
 - \$ ipa privilege-add "managing filesystems" --desc="for filesystems"
- 2. Assign the required permissions to the privilege group with the **privilege-add-permission** command

For example, to add the permissions named *managing automount* and *managing ftp services* to the *managing filesystems* privilege:

\$ ipa privilege-add-permission "managing filesystems" --permissions="managing automount" --permissions="managing ftp services"

31.5. COMMAND OPTIONS FOR EXISTING PRIVILEGES

Use the following variants to modify existing privileges as needed:

- To modify existing privileges, use the **ipa privilege-mod** command.
- To find existing privileges, use the **ipa privilege-find** command.
- To view a specific privilege, use the **ipa privilege-show** command.
- The **ipa privilege-remove-permission** command removes one or more permissions from a privilege.
- The **ipa privilege-del** command deletes a privilege completely.

Additional resources

- See the **ipa** man page on your system.
- See the **ipa help** command.

31.6. MANAGING IDM ROLES IN THE CLI

Follow this procedure to manage Identity Management (IdM) roles using the command line (CLI).

Prerequisites

- Administrator privileges for managing IdM or the **User Administrator** role.
- An active Kerberos ticket. For details, see Using kinit to log in to IdM manually.
- Existing privileges. For details about privileges, see Managing IdM privileges in the CLI.

Procedure

1. Add new role entries using the **ipa role-add** command:

\$ ipa role-add --desc="User Administrator" useradmin
-----Added role "useradmin"
------Role name: useradmin
Description: User Administrator

2. Add the required privileges to the role using the **ipa role-add-privilege** command:

\$ ipa role-add-privilege --privileges="user administrators" useradmin
Role name: useradmin
Description: User Administrator
Privileges: user administrators

Number of privileges added 1

3. Add the required members to the role using the **ipa role-add-member** command. Allowed member types are: users, groups, hosts and hostgroups.

For example, to add the group named *useradmins* to the previously created *useradmin* role:

\$ ipa role-add-member --groups=useradmins useradmin

Role name: useradmin

Description: User Administrator Member groups: useradmins Privileges: user administrators

Number of members added 1

31.7. COMMAND OPTIONS FOR EXISTING ROLES

Use the following variants to modify existing roles as needed:

- To modify existing roles, use the **ipa role-mod** command.
- To find existing roles, use the **ipa role-find** command.
- To view a specific role, use the **ipa role-show** command.
- To remove a member from the role, use the **ipa role-remove-member** command.
- The **ipa role-remove-privilege** command removes one or more privileges from a role.
- The **ipa role-del** command deletes a role completely.

- See the **ipa** man page on your system
- See the **ipa help** command.

CHAPTER 32. MANAGING ROLE-BASED ACCESS CONTROLS USING THE IDM WEB UI

Learn more about role-based access control (RBAC) in Identity Management (IdM). RBAC is a security feature that restricts access to authorized users. You can define roles with specific permissions and then assign those roles to users.

For general information about role-based access in IdM, see Role based access control in IdM.

32.1. MANAGING PERMISSIONS IN THE IDM WEB UI

Follow this procedure to manage permissions in Identity Management (IdM) using the web interface (IdM Web UI).

Prerequisites

- Administrator privileges for managing IdM or the **User Administrator** role.
- You are logged-in to the IdM Web UI. For details, see Accessing the IdM Web UI in a web browser.

Procedure

- To add a new permission, open the IPA Server>Role-Based Access Control submenu and select Permissions:
- 2. The list of permissions opens: Click the **Add** button at the top of the list of the permissions:
- 3. The **Add Permission** form opens. Specify the name of the new permission and define its properties.
- 4. Select the appropriate bind rule type:
 - permission is the default permission type, granting access through privileges and roles
 - all specifies that the permission applies to all authenticated users
 - anonymous specifies that the permission applies to all users, including unauthenticated users

NOTE

It is not possible to add permissions with a non-default bind rule type to privileges. You also cannot set a permission that is already present in a privilege to a non-default bind rule type.

- 5. Choose the rights to grant with this permission in Granted rights.
- 6. Define the method to identify the target entries for the permission:
 - Type specifies an entry type, such as user, host, or service. If you choose a value for the
 Type setting, a list of all possible attributes which will be accessible through this ACI for that
 entry type appears under Effective Attributes. Defining Type sets Subtree and Target
 DN to one of the predefined values.

- **Subtree** (required) specifies a subtree entry; every entry beneath this subtree entry is then targeted. Provide an existing subtree entry, as **Subtree** does not accept wildcards or non-existent domain names (DNs). For example: **cn=automount,dc=example,dc=com**
- Extra target filter uses an LDAP filter to identify which entries the permission applies to. The filter can be any valid LDAP filter, for example: (!(objectclass=posixgroup))

 IdM automatically checks the validity of the given filter. If you enter an invalid filter, IdM warns you about this when you attempt to save the permission.
- Target DN specifies the domain name (DN) and accepts wildcards. For example: uid=*,cn=users,cn=accounts,dc=com
- Member of group sets the target filter to members of the given group. After you specify
 the filter settings and click Add, IdM validates the filter. If all the permission settings are
 correct, IdM will perform the search. If some of the permissions settings are incorrect, IdM
 will display a message informing you about which setting is set incorrectly.

NOTE

Setting the **memberof** attribute permission is not applied if the target LDAP entry does not contain any reference to group membership.

- 7. Add attributes to the permission:
 - If you set **Type**, choose the **Effective attributes** from the list of available ACI attributes.
 - If you did not use **Type**, add the attributes manually by writing them into the **Effective** attributes field. Add a single attribute at a time; to add multiple attributes, click **Add** to add another input field.

IMPORTANT

If you do not set any attributes for the permission, then the permissions includes all attributes by default.

- 8. Finish adding the permissions with the **Add** buttons at the bottom of the form:
 - Click the Add button to save the permission and go back to the list of permissions.
 - To save the permission and continue adding additional permissions in the same form, click the Add and Add another button.
 - The **Add and Edit** button enables you to save and continue editing the newly created permission.
- 9. Optional: You can also edit the properties of an existing permission by clicking its name from the list of permissions to display the **Permission settings** page.
- 10. Optional: If you need to remove an existing permission, select the checkbox next to its name in the list and click the **Delete** button to display The **Remove permissions** dialog. Click **Delete**.

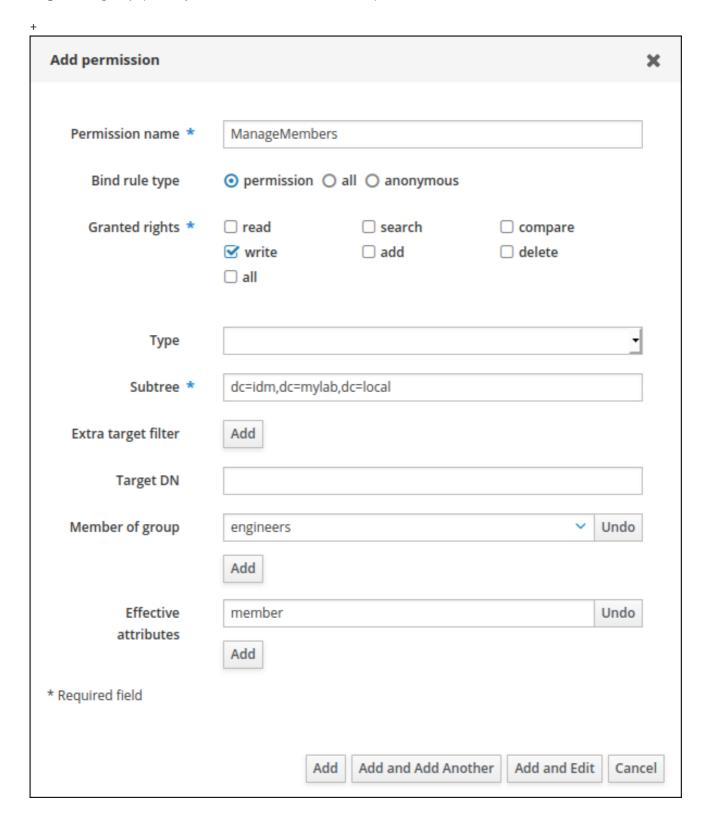

NOTE

Operations on default managed permissions are restricted: the attributes you cannot modify are disabled in the IdM Web UI and you cannot delete the managed permissions completely.

However, you can effectively disable a managed permission that has a bind type set to permission, by removing the managed permission from all privileges.

For example, the following shows how to configure the permission **write** on the **member** attribute in the **engineers** group (so they can add or remove members):

32.2. MANAGING PRIVILEGES IN THE IDM WEBUI

Follow this procedure to manage privileges in IdM using the web interface (IdM Web UI).

Prerequisites

- Administrator privileges for managing IdM or the **User Administrator** role.
- You are logged-in to the IdM Web UI. For details, see Accessing the IdM Web UI in a web browser.

Procedure

- 1. To add a new privilege, open the IPA Server>Role-Based Access Control submenu and select Privileges:
- 2. The list of privileges opens. Click the **Add** button at the top of the list of privileges.
- 3. The Add Privilege form opens. Enter the name and a description of the privilege.
- 4. Click the **Add and Edit** button to save the new privilege and continue to the privilege configuration page to add permissions.
- 5. Click the **Permissions** tab to display a list of permissions included in the selected privilege. Click the **Add** button at the top of the list to add permissions to the privilege:
- 6. Select the checkbox next to the name of each permission to add, and use the > button to move the permissions to the **Prospective** column.
- 7. Confirm by clicking the **Add** button.
- 8. Optional: If you need to remove permissions, select the checkbox next to the relevant permissions and click the **Delete** button to display the **Remove privileges from permissions** dialog. Click **Delete**.
- 9. Optional: If you need to delete an existing privilege, select the checkbox next to its name in the list and click the **Delete** button to open the **Remove privileges** dialog. Click **Delete**.

32.3. MANAGING ROLES IN THE IDM WEB UI

Follow this procedure to manage roles in Identity Management (IdM) using the web interface (IdM Web UI).

Prerequisites

- Administrator privileges for managing IdM or the **User Administrator** role.
- You are logged-in to the IdM Web UI. For details, see Accessing the IdM Web UI in a web browser.

Procedure

 To add a new role, open the IPA Server>Role-Based Access Control submenu and select Roles:

- 2. The list of roles opens. Click the **Add** button at the top of the list of roles.
- 3. The Add Role form opens. Enter the role name and a description:
- 4. Click the **Add and Edit** button to save the new role and continue to the role configuration page to add privileges and users.
- 5. Add members using the **Users**, **Users Groups**, **Hosts**, **Host Groups** or **Services** tabs, by clicking the **Add** button on top of the relevant list(s).
- 6. In the window that opens, select the members on the left and use the > button to move them to the **Prospective** column.
- 7. Select the **Privileges** tab and click **Add**.
- 8. Select the privileges on the left and use the > button to move them to the **Prospective** column.
- 9. Click the **Add** button to save.
- 10. Optional: If you need to remove privileges or members from a role, select the checkbox next to the name of the entity you want to remove and click the **Delete** button. A dialog opens. Click **Delete**.
- 11. Optional: If you need to remove an existing role, select the checkbox next to its name in the list and click the **Delete** button to display the **Remove roles** dialog. Click **Delete**.

CHAPTER 33. USING ANSIBLE PLAYBOOKS TO MANAGE ROLE-BASED ACCESS CONTROL IN IDM

Role-based access control (RBAC) is a policy-neutral access-control mechanism defined around roles and privileges. The components of RBAC in Identity Management (IdM) are roles, privileges and permissions:

- **Permissions** grant the right to perform a specific task such as adding or deleting users, modifying a group, and enabling read-access.
- Privileges combine permissions, for example all the permissions needed to add a new user.
- Roles grant a set of privileges to users, user groups, hosts or host groups.

Especially in large companies, using RBAC can help create a hierarchical system of administrators with their individual areas of responsibility.

Learn how you can use Ansible playbooks to manage role-based access control in the Using Ansible playbooks to manage role-based access control in IdM chapter of the *Using Ansible to install and manage Identity Management in RHEL 10* documentation.

- Preparing your environment for managing IdM using Ansible playbooks
- Permissions in IdM
- Privileges in IdM
- Roles in IdM

CHAPTER 34. USING ANSIBLE PLAYBOOKS TO MANAGE RBAC PRIVILEGES

Role-based access control (RBAC) is a policy-neutral access-control mechanism defined around roles, privileges, and permissions. Especially in large companies, using RBAC can help create a hierarchical system of administrators with their individual areas of responsibility.

Learn how you can use Ansible playbooks to manage RBAC privileges in Identity Management (IdM) in the Using Ansible playbooks to manage RBAC privileges chapter of the Using Ansible to install and manage Identity Management in RHEL 10 documentation.

- Preparing your environment for managing IdM using Ansible playbooks
- Permissions in IdM
- Privileges in IdM

CHAPTER 35. USING ANSIBLE PLAYBOOKS TO MANAGE RBAC PERMISSIONS IN IDM

Role-based access control (RBAC) is a policy-neutral access control mechanism defined around roles, privileges, and permissions. Especially in large companies, using RBAC can help create a hierarchical system of administrators with their individual areas of responsibility.

Learn how to manage RBAC permissions in Identity Management (IdM) using Ansible playbooks in the Using Ansible playbooks to manage RBAC permissions in IdM chapter of the Using Ansible to install and manage Identity Management in RHEL 10 documentation.

- Preparing your environment for managing IdM using Ansible playbooks
- Permissions in IdM
- Privileges in IdM

CHAPTER 36. USING AN ID VIEW TO OVERRIDE A USER ATTRIBUTE VALUE ON AN IDM CLIENT

If an Identity Management (IdM) user want to override some of their user or group attributes stored in the IdM LDAP server, for example the login name, home directory, certificate used for authentication, or **SSH** keys, you as IdM administrator can redefine these values on specific IdM clients by using IdM ID views. For example, you can specify a different home directory for a user on the IdM client that the user most commonly uses for logging in to IdM.

Learn how to redefine a POSIX attribute value associated with an IdM user on a host enrolled into IdM as a client.

36.1. ID VIEWS

An ID view in Identity Management (IdM) is an IdM client-side view specifying the following information:

- New values for centrally defined POSIX user or group attributes
- The client host or hosts on which the new values apply.

An ID view contains one or more overrides. An override is a specific replacement of a centrally defined POSIX attribute value.

You can only define an ID view for an IdM client centrally on IdM servers. You cannot configure client-side overrides for an IdM client locally.

For example, you can use ID views to achieve the following goals:

- Define different attribute values for different environments. For example, you can allow the IdM administrator or another IdM user to have different home directories on different IdM clients: you can configure /home/encrypted/username to be this user's home directory on one IdM client and /dropbox/username on another client. Using ID views in this situation is convenient as alternatively, for example, changing fallback_homedir, override_homedir or other home directory variables in the client's /etc/sssd/sssd.conf file would affect all users. See Adding an ID view to override an IdM user home directory on an IdM client for an example procedure.
- Replace a previously generated attribute value with a different value, such as overriding a user's UID. This ability can be useful when you want to achieve a system-wide change that would otherwise be difficult to do on the LDAP side, for example make 1009 the UID of an IdM user. IdM ID ranges, which are used to generate an IdM user UID, never start as low as 1000 or even 10000. If a reason exists for an IdM user to impersonate a local user with UID 1009 on all IdM clients, you can use ID views to override the UID of this IdM user that was generated when the user was created in IdM.

IMPORTANT

You can only apply ID views to IdM clients, not to IdM servers.

- Using ID views for Active Directory users
- SSSD Client-side View

36.2. POTENTIAL NEGATIVE IMPACT OF ID VIEWS ON SSSD PERFORMANCE

When you define an ID view, IdM places the desired override value in the IdM server's System Security Services Daemon (SSSD) cache. The SSSD running on an IdM client then retrieves the override value from the server cache.

Applying an ID view can have a negative impact on System Security Services Daemon (SSSD) performance, because certain optimizations and ID views cannot run at the same time. For example, ID views prevent SSSD from optimizing the process of looking up groups on the server:

- With ID views, SSSD must check every member on the returned list of group member names if the group name is overridden.
- Without ID views, SSSD can only collect the user names from the member attribute of the group object.

This negative effect becomes most apparent when the SSSD cache is empty or after you clear the cache, which makes all entries invalid.

36.3. ATTRIBUTES AN ID VIEW CAN OVERRIDE

ID views consist of user and group ID overrides. The overrides define the new POSIX attribute values.

User and group ID overrides can define new values for the following POSIX attributes:

User attributes

- Login name (**uid**)
- GECOS entry (gecos)
- UID number (uidNumber)
- GID number (**gidNumber**)
- Login shell (loginShell)
- Home directory (homeDirectory)
- SSH public keys (**ipaSshPubkey**)
- Certificate (userCertificate)

Group attributes

- Group name (**cn**)
- Group GID number (**gidNumber**)

36.4. GETTING HELP FOR ID VIEW COMMANDS

You can get help for commands involving Identity Management (IdM) ID views on the IdM command-line interface (CLI).

Prerequisites

• You have obtained a Kerberos ticket for an IdM user.

Procedure

• To display all commands used to manage ID views and overrides:

• To display detailed help for a particular command, add the **--help** option to the command:

```
$ ipa idview-add --help
Usage: ipa [global-options] idview-add NAME [options]

Add a new ID View.
Options:
-h, --help show this help message and exit
--desc=STR Description
[...]
```

36.5. USING AN ID VIEW TO OVERRIDE THE LOGIN NAME OF AN IDM USER ON A SPECIFIC HOST

Follow this procedure to create an ID view for a specific IdM client that overrides a POSIX attribute value associated with a specific IdM user. The procedure uses the example of an ID view that enables an IdM user named **idm_user** to log in to an IdM client named **host1** using the **user_1234** login name.

Prerequisites

• You are logged in as IdM administrator.

Procedure

1. Create a new ID view. For example, to create an ID view named **example_for_host1**:

```
$ ipa idview-add example_for_host1
-----
Added ID View "example_for_host1"
------
ID View Name: example_for_host1
```

2. Add a user override to the **example for host1** ID view. To override the user login:

- Enter the ipa idoverrideuser-add command
- Add the name of the ID view
- Add the user name, also called the anchor
- Add the **--login** option:

For a list of the available options, run ipa idoverrideuser-add --help.

NOTE

The **ipa idoverrideuser-add --certificate** command replaces all existing certificates for the account in the specified ID view. To append an additional certificate, use the **ipa idoverrideuser-add-cert** command instead:

\$ ipa idoverrideuser-add-cert example_for_host1 user -- certificate="MIIEATCC..."

- 3. Optional: Using the **ipa idoverrideuser-mod** command, you can specify new attribute values for an existing user override.
- 4. Apply **example_for_host1** to the **host1.idm.example.com** host:

\$ ipa idview-apply example_for_host1 --hosts=host1.idm.example.com

Applied ID View "example_for_host1"
-----hosts: host1.idm.example.com
-----Number of hosts the ID View was applied to: 1

NOTE

The **ipa idview-apply** command also accepts the **--hostgroups** option. The option applies the ID view to hosts that belong to the specified host group, but does not associate the ID view with the host group itself. Instead, the **--hostgroups** option expands the members of the specified host group and applies the **--hosts** option individually to every one of them.

This means that if a host is added to the host group in the future, the ID view does not apply to the new host.

- 5. To apply the new configuration to the **host1.idm.example.com** system immediately:
 - a. SSH to the system as root:

\$ ssh root@host1 Password:

b. Clear the SSSD cache:

root@host1 ~]# sss_cache -E

c. Restart the SSSD daemon:

root@host1 ~]# systemctl restart sssd

Verification

- If you have the credentials of user_1234, you can use them to log in to IdM on host1:
 - 1. SSH to **host1** using **user_1234** as the login name:

[root@r8server ~]# ssh user_1234@host1.idm.example.com Password:

Last login: Sun Jun 21 22:34:25 2020 from 192.168.122.229 [user_1234@host1 ~]\$

2. Display the working directory:

[user_1234@host1 ~]\$ **pwd** /home/idm_user/

 Alternatively, if you have root credentials on host1, you can use them to check the output of the id command for idm_user and user_1234:

```
[root@host1 ~]# id idm_user
uid=779800003(user_1234) gid=779800003(idm_user) groups=779800003(idm_user)
[root@host1 ~]# user_1234
uid=779800003(user_1234) gid=779800003(idm_user) groups=779800003(idm_user)
```

36.6. MODIFYING AN IDM ID VIEW

An ID view in Identity Management (IdM) overrides a POSIX attribute value associated with a specific IdM user. Follow this procedure to modify an existing ID view. Specifically, it describes how to modify an ID view to enable the user named <code>idm_user</code> to use the <code>/home/user_1234/</code> directory as the user home directory instead of <code>/home/idm_user/</code> on the <code>host1.idm.example.com</code> IdM client.

Prerequisites

- You have root access to **host1.idm.example.com**.
- You are logged in as a user with the required privileges, for example admin.
- You have an ID view configured for idm_user that applies to the host1 IdM client.

Procedure

1. As root, create the directory that you want **idm_user** to use on **host1.idm.example.com** as the user home directory:

[root@host1 /]# mkdir /home/user_1234/

2. Change the ownership of the directory:

[root@host1 /]# chown idm_user:idm_user /home/user_1234/

3. Display the ID view, including the hosts to which the ID view is currently applied. To display the ID view named **example_for_host1**:

\$ ipa idview-show example_for_host1 --all

dn: cn=example_for_host1,cn=views,cn=accounts,dc=idm,dc=example,dc=com

ID View Name: example_for_host1 User object override: idm_user

Hosts the view applies to: host1.idm.example.com

objectclass: ipaIDView, top, nsContainer

The output shows that the ID view currently applies to **host1.idm.example.com**.

- 4. Modify the user override of the **example_for_host1** ID view. To override the user home directory:
 - Enter the **ipa idoverrideuser-add** command
 - Add the name of the ID view
 - Add the user name, also called the anchor
 - Add the **--homedir** option:

```
$ ipa idoverrideuser-mod example_for_host1 idm_user -- homedir=/home/user_1234
```

Modified a User ID override "idm user"

Anchor to override: idm_user

User login: user 1234

Home directory: /home/user_1234/

For a list of the available options, run ipa idoverrideuser-mod --help.

- 5. To apply the new configuration to the **host1.idm.example.com** system immediately:
 - a. SSH to the system as root:

\$ ssh root@host1 Password:

b. Clear the SSSD cache:

root@host1 ~]# sss cache -E

c. Restart the SSSD daemon:

root@host1 ~]# systemctl restart sssd

Verification

1. **SSH** to **host1** as **idm_user**:

[root@r8server ~]# ssh idm_user@host1.idm.example.com Password:

Last login: Sun Jun 21 22:34:25 2020 from 192.168.122.229 [user_1234@host1 ~]\$

2. Print the working directory:

[user_1234@host1 ~]\$ **pwd** /home/user_1234/

Additional resources

• Defining global attributes for an AD user by modifying the Default Trust View

36.7. ADDING AN ID VIEW TO OVERRIDE AN IDM USER HOME DIRECTORY ON AN IDM CLIENT

An ID view in Identity Management (IdM) overrides a POSIX attribute value associated with a specific IdM user. Follow this procedure to create an ID view that applies to <code>idm_user</code> on an IdM client named <code>host1</code> to enable the user to use the <code>/home/user_1234/</code> directory as the user home directory instead of <code>/home/idm_user/</code>.

Prerequisites

- You have root access to **host1.idm.example.com**.
- You are logged in as a user with the required privileges, for example admin.

Procedure

1. As root, create the directory that you want **idm_user** to use on **host1.idm.example.com** as the user home directory:

[root@host1 /]# mkdir /home/user_1234/

2. Change the ownership of the directory:

[root@host1 /]# chown idm_user:idm_user /home/user_1234/

3. Create an ID view. For example, to create an ID view named example_for_host1:

\$ ipa idview-add example_for_host1

```
Added ID View "example_for_host1"
-----
ID View Name: example_for_host1
```

- 4. Add a user override to the **example_for_host1** ID view. To override the user home directory:
 - Enter the **ipa idoverrideuser-add** command
 - Add the name of the ID view
 - Add the user name, also called the anchor
 - Add the **--homedir** option:

5. Apply **example_for_host1** to the **host1.idm.example.com** host:

NOTE

The **ipa idview-apply** command also accepts the **--hostgroups** option. The option applies the ID view to hosts that belong to the specified host group, but does not associate the ID view with the host group itself. Instead, the **--hostgroups** option expands the members of the specified host group and applies the **--hosts** option individually to every one of them.

This means that if a host is added to the host group in the future, the ID view does not apply to the new host.

- 6. To apply the new configuration to the **host1.idm.example.com** system immediately:
 - a. SSH to the system as root:

\$ ssh root@host1 Password:

b. Clear the SSSD cache:

root@host1 ~]# sss_cache -E

c. Restart the SSSD daemon:

root@host1 ~]# systemctl restart sssd

Verification

1. SSH to host1 as idm user:

[root@r8server ~]# **ssh idm_user@host1.idm.example.com**Password:
Activate the web console with: systemctl enable --now cockpit.socket
Last login: Sun Jun 21 22:34:25 2020 from 192.168.122.229
[idm_user@host1 /]\$

2. Print the working directory:

[idm_user@host1 /]\$ **pwd** /home/user_1234/

Additional resources

• Overriding Default Trust View attributes for an AD user on an IdM client with an ID view

36.8. APPLYING AN ID VIEW TO AN IDM HOST GROUP

The **ipa idview-apply** command accepts the **--hostgroups** option. However, the option acts as a one-time operation that applies the ID view to hosts that currently belong to the specified host group, but does not dynamically associate the ID view with the host group itself. The **--hostgroups** option expands the members of the specified host group and applies the **--hosts** option individually to every one of them.

If you add a new host to the host group later, you must apply the ID view to the new host manually, using the **ipa idview-apply** command with the **--hosts** option.

Similarly, if you remove a host from a host group, the ID view is still assigned to the host after the removal. To unapply the ID view from the removed host, you must run the **ipa idview-unapply** *id view name --hosts=name of the removed host* command.

Follow this procedure to achieve the following goals:

- 1. How to create a host group and add hosts to it.
- 2. How to apply an ID view to the host group.
- 3. How to add a new host to the host group and apply the ID view to the new host.

Prerequisites

• Ensure that the ID view you want to apply to the host group exists in IdM. For example, to create an ID view to override the GID for an AD user, see Overriding Default Trust View attributes for an AD user on an IdM client with an ID view

Procedure

- 1. Create a host group and add hosts to it:
 - a. Create a host group. For example, to create a host group named baltimore:

b. Add hosts to the host group. For example, to add the **host102** and **host103** to the **baltimore** host group:

2. Apply an ID view to the hosts in the host group. For example, to apply the **example_for_host1** ID view to the **baltimore** host group:

```
[root@server ~]# ipa idview-apply --hostgroups=baltimore
ID View Name: example_for_host1
-------
Applied ID View "example_for_host1"
------
hosts: host102.idm.example.com, host103.idm.example.com
-------
Number of hosts the ID View was applied to: 2
```

- 3. Add a new host to the host group and apply the ID view to the new host:
 - a. Add a new host to the host group. For example, to add the **somehost.idm.example.com** host to the **baltimore** host group:

b. Optional: Display the ID view information. For example, to display the details about the **example_for_host1** ID view:

```
[root@server ~]# ipa idview-show example_for_host1 --all
dn: cn=example_for_host1,cn=views,cn=accounts,dc=idm,dc=example,dc=com
ID View Name: example_for_host1
[...]
Hosts the view applies to: host102.idm.example.com, host103.idm.example.com
objectclass: ipaIDView, top, nsContainer
```

The output shows that the ID view is not applied to **somehost.idm.example.com**, the newly-added host in the **baltimore** host group.

c. Apply the ID view to the new host. For example, to apply the **example_for_host1** ID view to **somehost.idm.example.com**:

```
[root@server ~]# ipa idview-apply --host=somehost.idm.example.com
ID View Name: example_for_host1
-------
Applied ID View "example_for_host1"
------
hosts: somehost.idm.example.com
------
Number of hosts the ID View was applied to: 1
```

Verification

Display the ID view information again:

```
[root@server ~]# ipa idview-show example_for_host1 --all
dn: cn=example_for_host1,cn=views,cn=accounts,dc=idm,dc=example,dc=com
ID View Name: example_for_host1
[...]
Hosts the view applies to: host102.idm.example.com, host103.idm.example.com,
somehost.idm.example.com
objectclass: ipaIDView, top, nsContainer
```

The output shows that ID view is now applied to **somehost.idm.example.com**, the newly-added host in the **baltimore** host group.

36.9. MIGRATING NIS DOMAINS TO IDENTITY MANAGEMENT

You can use ID views to set host specific UIDs and GIDs for existing hosts to prevent changing permissions for files and directories when migrating NIS domains into IdM.

Prerequisites

• You authenticated yourself as an admin using the **kinit admin** command.

Procedure

- 1. Add users and groups in the IdM domain.
 - a. Create users using the **ipa user-add** command. For more information, see Adding users to IdM.

- b. Create groups using the **ipa group-add** command. For more information see: Adding groups to IdM.
- 2. Override IDs IdM generated during the user creation:
 - a. Create a new ID view using **ipa idview-add** command. For more information see: Getting help for ID view commands.
 - b. Add ID overrides for the users and groups to the ID view using **ipa idoverrideuser-add** and **idoverridegroup-add** respectively.
- 3. Assign the ID view to the specific hosts using **ipa idview-apply** command.
- 4. Decommission the NIS domains.

Verification

1. To check if all users and groups were added to the ID view correctly, use the **ipa idview-show** command

\$ ipa idview-show example-view

ID View Name: example-view

User object overrides: example-user1
Group object overrides: example-group

36.10. USING ANSIBLE TO OVERRIDE THE LOGIN NAME AND HOME DIRECTORY OF AN IDM USER ON A SPECIFIC HOST

Complete this procedure to use the **idoverrideuser ansible-freeipa** module to create an ID view for a specific Identity Management (IdM) client that overrides a POSIX attribute value associated with a specific IdM user. The procedure uses the example of an ID view that enables an IdM user named **idm_user** to log in to an IdM client named **host1.idm.example.com** by using the **user_1234** login name. Additionally, the ID view modifies the home directory of idm_user so that after logging in to host1, the user home directory is **/home/user_1234/**.

Prerequisites

- On the control node:
 - You are using Ansible version 2.15 or later.
 - You have installed the **freeipa.ansible freeipa** collection.
 - The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.
 - The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin_password** and that you have access to a file that stores the password protecting the **secret.yml** file.
- The target node, that is the node on which the **freeipa.ansible_freeipa** module is executed, is part of the IdM domain as an IdM client, server or replica.

Procedure

1. Create your Ansible playbook file **add-idoverrideuser-with-name-and-homedir.yml** with the following content:

```
- name: Playbook to manage idoverrideuser
 hosts: ipaserver
 become: false
 gather facts: false
 vars_files:
 - /home/user_name/MyPlaybooks/secret.yml
 tasks:
 - name: Ensure idview_for_host1 is present
  idview:
   ipaadmin_password: "{{ ipaadmin_password }}"
   name: idview_for_host1
 - name: Ensure idview_for_host1 is applied to host1.idm.example.com
  idview:
   ipaadmin_password: "{{ ipaadmin_password }}"
   name: idview for host1
   host: host1.idm.example.com
   action: member
 - name: Ensure idm_user is present in idview_for_host1 with homedir /home/user_1234
and name user 1234
  ipaidoverrideuser:
   ipaadmin_password: "{{ ipaadmin_password }}"
   idview: idview_for_host1
   anchor: idm_user
   name: user_1234
   homedir: /home/user_1234
```

2. Run the playbook. Specify the playbook file, the file storing the password protecting the secret.yml file, and the inventory file::

```
$ ansible-playbook --vault-password-file=password_file -v -i <path_to_inventory_directory>/inventory <path_to_playbooks_directory>/add-idoverrideuser-with-name-and-homedir.yml
```

- 3. Optional: If you have **root** credentials, you can apply the new configuration to the **host1.idm.example.com** system immediately:
 - a. SSH to the system as **root**:

```
$ ssh root@host1
Password:
```

b. Clear the SSSD cache:

```
root@host1 ~]# sss_cache -E
```

c. Restart the SSSD daemon:

root@host1 ~]# systemctl restart sssd

Verification

1. SSH to host1 as idm_user:

[root@r8server ~]# ssh idm_user@host1.idm.example.com Password:

Last login: Sun Jun 21 22:34:25 2020 from 192.168.122.229 [user_1234@host1 ~]\$

2. Print the working directory:

[user_1234@host1 ~]\$ **pwd**/home/user_1234/

Additional resources

• The idoverrideuser module in **ansible-freeipa** upstream docs

36.11. USING ANSIBLE TO CONFIGURE AN ID VIEW THAT ENABLES AN SSH KEY LOGIN ON AN IDM CLIENT

Complete this procedure to use the **idoverrideuser ansible-freeipa** module to ensure that an IdM user can use a specific SSH key to log in to a specific IdM client. The procedure uses the example of an ID view that enables an IdM user named **idm_user** to log in to an IdM client named **host1.idm.example.com** with an SSH key.

NOTE

This ID view can be used to enhance a specific HBAC rule.

Prerequisites

- On the control node:
 - You are using Ansible version 2.15 or later.
 - You have installed the **freeipa.ansible_freeipa** collection.
 - The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.
 - The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin_password** and that you have access to a file that stores the password protecting the **secret.yml** file.
- The target node, that is the node on which the **freeipa.ansible_freeipa** module is executed, is part of the IdM domain as an IdM client, server or replica.'s SSH public key.
- The idview for host1 ID view exists.
- The target node, that is the node on which the freeipa.ansible_freeipa module is executed, is part of the IdM domain as an IdM client, server or replica.

Procedure

1. Create your Ansible playbook file **ensure-idoverrideuser-can-login-with-sshkey.yml** with the following content:

- name: Playbook to manage idoverrideuser

hosts: ipaserver become: false gather_facts: false vars_files:

- /home/user name/MyPlaybooks/secret.yml

tasks:

- name: Ensure test user idm_user is present in idview idview_for_host1 with sshpubkey ipaidoverrideuser:

```
ipaadmin_password: "{{ ipaadmin_password }}"
idview: idview_for_host1
anchor: idm_user
sshpubkey:
```

- ssh-rsa AAAAB3NzaC1yc2EAAADAQABAAABgQCqmVDpEX5gnSjKuv97Ay ...
- name: Ensure idview_for_host1 is applied to host1.idm.example.com ipaidview:

```
ipaadmin_password: "{{ ipaadmin_password }}"
```

name: idview_for_host1

host: host1.idm.example.com

action: member

2. Run the playbook. Specify the playbook file, the file storing the password protecting the secret.yml file, and the inventory file:

```
$ ansible-playbook --vault-password_file=password_file -v -i <path_to_inventory_directory>/inventory <path_to_playbooks_directory>/ensure-idoverrideuser-can-login-with-sshkey.yml
```

- 3. Optional: If you have **root** credentials, you can apply the new configuration to the **host1.idm.example.com** system immediately:
 - a. SSH to the system as **root**:

```
$ ssh root@host1
Password:
```

b. Clear the SSSD cache:

```
root@host1 ~]# sss_cache -E
```

c. Restart the SSSD daemon:

root@host1 ~]# systemctl restart sssd

Verification

• Use the public key to **SSH** to **host1**:

[root@r8server ~]# ssh -i ~/.ssh/id_rsa.pub idm_user@host1.idm.example.com

Last login: Sun Jun 21 22:34:25 2023 from 192.168.122.229 [idm_user@host1 ~]\$

The output confirms that you have logged in successfully.

Additional resources

• The idoverrideuser module in **ansible-freeipa** upstream docs

36.12. USING ANSIBLE TO GIVE A USER ID OVERRIDE ACCESS TO THE LOCAL SOUND CARD ON AN IDM CLIENT

You can use the **ansible-freeipa group** and **idoverrideuser** modules to make Identity Management (IdM) or Active Directory (AD) users members of the local **audio** group on an IdM client. This grants the IdM or AD users privileged access to the sound card on the host. The procedure uses the example of the **Default Trust View** ID view to which the **aduser@addomain.com** ID override is added in the first playbook task. In the next playbook task, an **audio** group is created in IdM with the GID of 63, which corresponds to the GID of local **audio** groups on RHEL hosts. At the same time, the **aduser@addomain.com** ID override is added to the IdM audio group as a member.

Prerequisites

- You have **root** access to the IdM client on which you want to perform the first part of the procedure. In the example, this is **client.idm.example.com**.
- You have configured your Ansible control node to meet the following requirements:
 - You are using Ansible version 2.15 or later.
 - You have installed the **freeipa.ansible_freeipa** collection.
 - The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.
 - The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin_password** and that you have access to a file that stores the password protecting the **secret.yml** file.
- The target node, that is the node on which the **freeipa.ansible_freeipa** module is executed, is part of the IdM domain as an IdM client, server or replica.@addomain.com*.
- The target node, that is the node on which the freeipa.ansible_freeipa module is executed, is part of the IdM domain as an IdM client, server or replica.

Procedure

On client.idm.example.com, add [SUCCESS=merge] to the /etc/nsswitch.conf file:

[...]
Allow initgroups to default to the setting for group.
initgroups: sss [SUCCESS=merge] files

2. Identify the GID of the local **audio** group:

\$ getent group audio

.....

audio:x:63

3. On your Ansible control node, create an **add-aduser-to-audio-group.yml** playbook with a task to add the **aduser@addomain.com** user override to the Default Trust View:

- name: Playbook to manage idoverrideuser

hosts: ipaserver become: false

tasks:

- name: Add aduser@addomain.com user to the Default Trust View

ipaidoverrideuser:

ipaadmin_password: "{{ ipaadmin_password }}"

idview: "Default Trust View" anchor: aduser@addomain.com

- 4. Use another playbook task in the same playbook to add the group **audio** to IdM with the **GID** of 63. Add the aduser idoverrideuser to the group:
 - name: Add the audio group with the aduser member and GID of 63 ipagroup:

ipaadmin_password: "{{ ipaadmin_password }}"

name: audio idoverrideuser:

- aduser@addomain.com

gidnumber: 63

- 5. Save the file.
- 6. Run the Ansible playbook. Specify the playbook file, the file storing the password protecting the **secret.yml** file, and the inventory file:

\$ ansible-playbook --vault-password-file=password_file -v -i inventory add-aduser-to-audio-group.yml

Verification

1. Log in to the IdM client as the AD user:

\$ ssh aduser@addomain.com@client.idm.example.com

2. Verify the group membership of the AD user:

\$ id aduser@addomain.com uid=702801456(aduser@addomain.com) gid=63(audio) groups=63(audio)

Additional resources

• The idoverrideuser and ipagroup **ansible-freeipa** upstream documentation

36.13. USING ANSIBLE TO ENSURE AN IDM USER IS PRESENT IN AN ID VIEW WITH A SPECIFIC UID

If you are working in a lab where you have our own computer but your /home/ directory is in a shared drive exported by a server, you can have two users:

- One that is system-wide user, stored centrally in Identity Management (IdM).
- One whose account is local, that is stored on the system in question.

If you need to have full access to your files whether you are logged in as an IdM user or as a local user, you can do so by giving both users the same **UID**.

Complete this procedure to use the **ansible-freeipa idoverrideuser** module to:

- Apply an ID view to host01 named idview_for_host01.
- Ensure, in idview_for_hostO1, the presence of a user ID override for idm_user with the **UID** of **20001**.

Prerequisites

- You have configured your Ansible control node to meet the following requirements:
 - You are using Ansible version 2.15 or later.
 - You have installed the **freeipa.ansible_freeipa** collection.
 - The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.
 - The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin_password** and that you have access to a file that stores the password protecting the **secret.yml** file.
- The target node, that is the node on which the **freeipa.ansible_freeipa** module is executed, is part of the IdM domain as an IdM client, server or replica.+

- name: Ensure both local user and IdM user have access to same files

hosts: ipaserver become: false gather_facts: false

tasks:

- name: Ensure idview_for_host1 is applied to host1.idm.example.com ipaidview:

ipaadmin_password: "{{ ipaadmin_password }}"
name: *idview_for_host01*
host: *host1.idm.example.com*

- name: Ensure idmuser is present in idview_for_host01 with the UID of 20001 ipaidoverrideuser:

ipaadmin_password: "{{ ipaadmin_password }}"

idview: *idview_for_host01*

anchor: *idm_user*

UID: 20001

+ . Save the file.

+ . Run the playbook. Specify the playbook file, the file storing the password protecting the **secret.yml** file, and the inventory file:

+

\$ ansible-playbook --vault-password-file=password_file -v -i inventory ensure-idmuser-and-local-user-have-access-to-same-files.yml

Additional resources

• The idoverrideuser module in **ansible-freeipa** upstream docs

36.14. USING ANSIBLE TO ENSURE AN IDM USER CAN LOG IN TO AN IDM CLIENT WITH TWO CERTIFICATES

If you want an Identity Management (IdM) user that normally logs in to IdM with a password to authenticate to a specific IdM client by using a smart card only, you can create an ID view that requires certification for the user on that client.

Complete this procedure to use the **ansible-freeipa idoverrideuser** module to:

- Apply an ID view to host01 named idview_for_host01.
- Ensure, in idview_for_hostO1, the presence of a user ID override for idm_user with two certificates.

Prerequisites

- You have configured your Ansible control node to meet the following requirements:
 - You are using Ansible version 2.15 or later.
 - You have installed the **freeipa.ansible_freeipa** collection.
 - The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.
 - The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin_password** and that you have access to a file that stores the password protecting the **secret.yml** file.
- The target node, that is the node on which the **freeipa.ansible_freeipa** module is executed, is part of the IdM domain as an IdM client, server or replica.+

- name: Ensure both local user and IdM user have access to same files

hosts: ipaserver become: false gather_facts: false tasks:

name: Ensure idview_for_host1 is applied to host01.idm.example.com ipaidview:
ipaadmin_password: "{{ ipaadmin_password }}"
name: *idview_for_host01*
host: *host01.idm.example.com*
name: Ensure an IdM user is present in ID view with two certificates ipaidoverrideuser:
ipaadmin_password: "{{ ipaadmin_password }}"
idview: *idview_for_host01*
anchor: *idm_user*
certificate:
 "{{ lookup('file', 'cert1.b64', rstrip=False) }}"
 "{{ lookup('file', 'cert2.b64', rstrip=False) }}"

- + The **rstrip=False** directive causes the white space not to be removed from the end of the looked-up
- + . Save the file.
- + . Run the playbook. Specify the playbook file, the file storing the password protecting the **secret.yml** file, and the inventory file:

+

 $\$ \ ansible-playbook \ --vault-password-file=password_file \ -v \ -i \ inventory \ ensure-idmuser-present-in-idview-with-certificates.yml$

Additional resources

• The idoverrideuser module in **ansible-freeipa** upstream docs

36.15. USING ANSIBLE TO GIVE AN IDM GROUP ACCESS TO THE SOUND CARD ON AN IDM CLIENT

You can use the **ansible-freeipa idview** and **idoverridegroup** modules to make Identity Management (IdM) or Active Directory (AD) users members of the local **audio** group on an IdM client. This grants the IdM or AD users privileged access to the sound card on the host.

The procedure uses the example of the <code>idview_for_host01</code> ID view to which the <code>audio</code> group ID override is added with the <code>GID</code>` of <code>63</code>, which corresponds to the GID of local <code>audio</code> groups on RHEL hosts. The <code>idview_for_host01</code> ID view is applied to an IdM client named <code>host01.idm.example.com</code>.

Prerequisites

- You have configured your Ansible control node to meet the following requirements:
 - You are using Ansible version 2.15 or later.
 - You have installed the **freeipa.ansible freeipa** collection.
 - The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.

- The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin_password** and that you have access to a file that stores the password protecting the **secret.yml** file.
- The target node, that is the node on which the freeipa.ansible_freeipa module is executed, is part of the IdM domain as an IdM client, server or replica.+

```
$ *getent group audio*
-----
audio:x:63
```

1. On your Ansible control node, create an **give-idm-group-access-to-sound-card-on-idm-client.yml** playbook with the following tasks:

 name: Playbook to give IdM group access to sound card on IdM client hosts: ipaserver become: false

tasks:

 name: Ensure idview_for_host01 exists and is applied to host01.idm.example.com ipaidview:

ipaadmin_password: "{{ ipaadmin_password }}"
name: idview_for_host01
host: host01.idm.example.com

- name: Add an override for the IdM audio group with GID 63 to idview_for_host01 ipaidoverridegroup:

ipaadmin_password: "{{ ipaadmin_password }}"

idview: idview_for_host01

anchor: audio GID: 63

- 2. Save the file.
- 3. Run the Ansible playbook. Specify the playbook file, the file storing the password protecting the **secret.yml** file, and the inventory file:

\$ ansible-playbook --vault-password-file=password_file -v -i inventory give-idm-group-access-to-sound-card-on-idm-client.yml

Verification

1. On an IdM client, obtain IdM administrator's credentials:

\$ kinit admin Password:

2. Create a test IdM user:

- 3. Add the user to the IdM audio group:
 - \$ ipa group-add-member --tuser audio
- 4. Log in to host01.idm.example.com as tuser:
 - \$ ssh tuser@host01.idm.example.com
- 5. Verify the group membership of the user:

```
$ id tuser
uid=702801456(tuser) gid=63(audio) groups=63(audio)
```

- The idoverridegroup, idview and ipagroup **ansible-freeipa** upstream documentation
- Enabling group merging for local and remote groups in IdM

CHAPTER 37. USING ID VIEWS FOR ACTIVE DIRECTORY USERS

You can use ID views to specify new values for the POSIX attributes of your Active Directory (AD) users in an IdM-AD Trust environment.

By default, IdM applies the **Default Trust View** to all AD users. You can configure additional ID views on individual IdM clients to further adjust which POSIX attributes specific users receive.

37.1. HOW THE DEFAULT TRUST VIEW WORKS

The **Default Trust View** is the default ID view that is always applied to AD users and groups in trust-based setups. It is created automatically when you establish the trust using the **ipa-adtrust-install** command and cannot be deleted.

NOTE

The Default Trust View only accepts overrides for AD users and groups, not for IdM users and groups.

Using the Default Trust View, you can define custom POSIX attributes for AD users and groups, thus overriding the values defined in AD.

Table 37.1. Applying the Default Trust View

	Values in AD	Default Trust View	Result
Login	ad_user	ad_user	ad_user
UID	111	222	222
GID	111	(no value)	111

You can also configure additional ID Views to override the Default Trust View on IdM clients. IdM applies the values from the host-specific ID view on top of the Default Trust View:

- If an attribute is defined in the host-specific ID view, IdM applies the value from this ID view.
- If an attribute is not defined in the host-specific ID view, IdM applies the value from the Default Trust View.

Table 37.2. Applying a host-specific ID view on top of the Default Trust View

	Values in AD	Default Trust View	Host-specific ID view	Result
Login	ad_user	ad_user	(no value)	ad_user
UID	111	222	333	333

	Values in AD	Default Trust View	Host-specific ID view	Result
GID	111	(no value)	333	333

NOTE

You can only apply host-specific ID views to override the Default Trust View on IdM clients. IdM servers and replicas always apply the values from the Default Trust View.

Additional resources

• Using an ID view to override a user attribute value on an IdM client

37.2. DEFINING GLOBAL ATTRIBUTES FOR AN AD USER BY MODIFYING THE DEFAULT TRUST VIEW

If you want to override a POSIX attribute for an Active Directory (AD) user throughout your entire IdM deployment, modify the entry for that user in the Default Trust View. This procedure sets the GID for the AD user **ad user@ad.example.com** to 732000006.

Prerequisites

- You have authenticated as an IdM administrator.
- A group must exist with the GID or you must set the GID in an ID override for a group.

Procedure

1. As an IdM administrator, create an ID override for the AD user in the Default Trust View that changes the GID number to 732000006:

ipa idoverrideuser-add 'Default Trust View' ad_user@ad.example.com -- gidnumber=732000006

2. Clear the entry for the **ad_user@ad.example.com** user from the SSSD cache on all IdM servers and clients. This removes stale data and allows the new override value to apply.

sssctl cache-expire -u ad_user@ad.example.com

Verification

 Retrieve information for the ad_user@ad.example.com user to verify the GID reflects the updated value.

id ad user@ad.example.com

uid=702801456(ad_user@ad.example.com) **gid=732000006(ad_admins)** groups=732000006(ad_admins),702800513(domain users@ad.example.com)

37.3. OVERRIDING DEFAULT TRUST VIEW ATTRIBUTES FOR AN AD USER ON AN IDM CLIENT WITH AN ID VIEW

You might want to override some POSIX attributes from the Default Trust View for an Active Directory (AD) user. For example, you might need to give an AD user a different GID on one particular IdM client. You can use an ID view to override a value from the Default Trust View for an AD user and apply it to a single host. This procedure explains how to set the GID for the **ad_user@ad.example.com** AD user on the **host1.idm.example.com** IdM client to 732001337.

Prerequisites

- You have root access to the **host1.idm.example.com** IdM client.
- You are logged in as a user with the required privileges, for example the **admin** user.

Procedure

1. Create an ID view. For example, to create an ID view named example_for_host1:

```
$ ipa idview-add example_for_host1
------
Added ID View "example_for_host1"
------
ID View Name: example_for_host1
```

- 2. Add a user override to the **example_for_host1** ID view. To override the user's GID:
 - Enter the ipa idoverrideuser-add command
 - Add the name of the ID view
 - Add the user name, also called the anchor
 - Add the **--gidnumber=** option:

3. Apply **example for host1** to the **host1.idm.example.com** IdM client:

NOTE

The **ipa idview-apply** command also accepts the **--hostgroups** option. The option applies the ID view to hosts that belong to the specified host group, but does not associate the ID view with the host group itself. Instead, the **--hostgroups** option expands the members of the specified host group and applies the **--hosts** option individually to every one of them.

This means that if a host is added to the host group in the future, the ID view does not apply to the new host.

 Clear the entry for the ad_user@ad.example.com user from the SSSD cache on the host1.idm.example.com IdM client. This removes stale data and allows the new override value to apply.

[root@host1 ~]# sssctl cache-expire -u ad_user@ad.example.com

Verification

- 1. **SSH** to **host1** as **ad_user@ad.example.com**:
 - [root@r8server ~]# ssh ad_user@ad.example.com@host1.idm.example.com
- 2. Retrieve information for the **ad_user@ad.example.com** user to verify the GID reflects the updated value.

[ad_user@ad.example.com@host1 ~]\$ id ad_user@ad.example.com uid=702801456(ad_user@ad.example.com) gid=732001337(admins2) groups=732001337(admins2),702800513(domain users@ad.example.com)

CHAPTER 38. ADJUSTING ID RANGES MANUALLY

An IdM server generates unique user ID (UID) and group ID (GID) numbers. By creating and assigning different ID ranges to replicas, it also ensures that they never generate the same ID numbers. By default, this process is automatic. However, you can manually adjust the IdM ID range during the IdM server installation, or manually define a replica's DNA ID range.

38.1. ID RANGES

ID numbers are divided into *ID ranges*. Keeping separate numeric ranges for individual servers and replicas eliminates the chance that an ID number issued for an entry is already used by another entry on another server or replica.

Note that there are two distinct types of ID ranges:

- The IdM *ID range*, which is assigned during the installation of the first server. This range cannot be modified after it is created. However, you can create a new IdM ID range in addition to the original one. For more information, see Automatic ID ranges assignment and Adding a new IdM ID range.
- The *Distributed Numeric Assignment* (DNA) ID ranges, which can be modified by the user.
 These have to fit within an existing IdM ID range. For more information, see Assigning DNA ID ranges manually.

Replicas can also have a **next** DNA ID range assigned. A replica uses its next range when it runs out of IDs in its current range. Next ranges are not assigned automatically when a replica is deleted and you must assign them manually.

The ranges are updated and shared between the server and replicas by the DNA plug-in, as part of the back end 389 Directory Server instance for the domain.

The DNA range definition is set by two attributes:

- The server's next available number: the low end of the DNA range
- The range size: the number of ID's in the DNA range

The initial bottom range is set during the plug-in instance configuration. After that, the plug-in updates the bottom value. Breaking the available numbers into ranges allows the servers to continually assign numbers without overlapping with each other.

38.2. AUTOMATIC ID RANGES ASSIGNMENT

IdM ID ranges

By default, an IdM ID range is automatically assigned during the IdM server installation. The **ipa-server-install** command randomly selects and assigns a range of 200,000 IDs from a total of 10,000 possible ranges. Selecting a random range in this way significantly reduces the probability of conflicting IDs in case you decide to merge two separate IdM domains in the future.

NOTE

This IdM ID range cannot be modified after it is created. You can only manually adjust the Distributed Numeric Assignment (DNA) ID ranges, using the commands described in Assigning DNA ID ranges manually. A DNA range matching the IdM ID range is automatically created during installation.

DNA ID ranges

If you have a single IdM server installed, it controls the whole DNA ID range. When you install a new replica and the replica requests its own DNA ID range, the initial ID range for the server splits and is distributed between the server and replica: the replica receives half of the remaining DNA ID range that is available on the initial server. The server and replica then use their respective portions of the original ID range for new user or group entries. Also, if the replica is close to depleting its allocated ID range and fewer than 100 IDs remain, the replica contacts the other available servers to request a new DNA ID range.

IMPORTANT

When you install a replica, it **does not** immediately receive an ID range. A replica receives an ID range the first time the DNA plug-in is used, for example when you first add a user.

If the initial server stops functioning before the replica requests a DNA ID range from it, the replica is unable to contact the server to request the ID range. Attempting to add a new user on the replica then fails. In such situations, you can find out what ID range is assigned to the disabled server , and assign an ID range to the replica manually.

38.3. ASSIGNING THE IDM ID RANGE MANUALLY DURING SERVER INSTALLATION

You can override the default behavior and set an IdM ID range manually instead of having it assigned randomly.

IMPORTANT

Do not set ID ranges that include UID values of 1000 and lower; these values are reserved for system use. Also, do not set an ID range that would include the 0 value; the SSSD service does not handle the 0 ID value.

Procedure

- You can define the IdM ID range manually during server installation by using the following two options with **ipa-server-install**:
 - --idstart gives the starting value for UID and GID numbers.
 - **--idmax** gives the maximum UID and GID number; by default, the value is the **--idstart** starting value plus 199,999.

Verification

• To check if the ID range was assigned correctly, you can display the assigned IdM ID range by using the **ipa idrange-find** command:

ipa idrange-find

1 range matched

Range name: IDM.EXAMPLE.COM_id_range First Posix ID of the range: 882200000

Number of IDs in the range: 200000

Range type: local domain range
----Number of entries returned 1

38.4. ADDING A NEW IDM ID RANGE

In some cases, you may want to create a new IdM ID range in addition to the original one; for example, when a replica has run out of IDs and the original IdM ID range is depleted.

IMPORTANT

Adding a new IdM ID range does not create new DNA ID ranges automatically. You must assign new DNA ID ranges to replicas manually as needed. For more information about how to do this, see assigning DNA ID ranges manually.

Procedure

1. To create a new IdM ID range, use the **ipa idrange-add** command. You must specify the new range name, the first ID number of the range, the range size, and the first RID number of the primary and secondary RID range:

ipa idrange-add IDM.EXAMPLE.COM_new_range --base-id 5000 --range-size 1000 --rid-base 300000 --secondary-rid-base 1300000 --type ipa-local

ipa: WARNING: Service dirsrv@IDM-EXAMPLE-COM.service requires restart on IPA server <all IPA servers> to apply configuration changes.

Added ID range "IDM.EXAMPLE.COM_new_range"

Range name: IDM.EXAMPLE.COM_new_range

First Posix ID of the range: 5000 Number of IDs in the range: 1000

First RID of the corresponding RID range: 300000 First RID of the secondary RID range: 1300000

Range type: local domain range

2. Restart the Directory Server service on all IdM servers in the deployment:

systemctl restart dirsrv@IDM-EXAMPLE-COM.service

This ensures that when you create users with UIDs from the new range, they have security identifiers (SIDs) assigned.

- 3. Optional: Update the ID range immediately:
 - a. Clear the System Security Services Daemon (SSSD) cache:

sss_cache -E

b. Restart the SSSD daemon:

systemctl restart sssd

NOTE

If you do not clear the SSSD cache and restart the service, SSSD only detects the new ID range when it updates the domain list and other configuration data stored on the IdM server.

Verification

• You can check if the new range is set correctly by using the **ipa idrange-find** command:

ipa idrange-find

2 ranges matched

.....

Range name: IDM.EXAMPLE.COM_id_range First Posix ID of the range: 882200000 Number of IDs in the range: 200000 Range type: local domain range

Range name: IDM.EXAMPLE.COM_new_range

First Posix ID of the range: 5000 Number of IDs in the range: 1000

First RID of the corresponding RID range: 300000 First RID of the secondary RID range: 1300000

Range type: local domain range

Number of entries returned 2

38.5. THE ROLE OF SECURITY AND RELATIVE IDENTIFIERS IN IDM ID RANGES

An Identity Management (IdM) ID range is defined by several parameters:

- The range name
- The first POSIX ID of the range
- The range size: the number of IDs in the range
- The first relative identifier (RID) of the corresponding RID range
- The first RID of the **secondary RID range**

You can view these values by using the **ipa idrange-show** command:

\$ ipa idrange-show IDM.EXAMPLE.COM id range

Range name: IDM.EXAMPLE.COM_id_range

First Posix ID of the range: 196600000 Number of IDs in the range: 200000

First RID of the corresponding RID range: 1000 First RID of the secondary RID range: 1000000

Range type: local domain range

Security identifiers

The data from the ID ranges of the local domain are used by the IdM server internally to assign unique **security identifiers** (SIDs) to IdM users and groups. The SIDs are stored in the user and group objects. A user's SID consists of the following:

- The domain SID
- The user's **relative identifier** (RID), which is a four-digit 32-bit value appended to the domain SID

For example, if the domain SID is S-1-5-21-123-456-789 and the RID of a user from this domain is 1008, then the user has the SID of S-1-5-21-123-456-789-1008.

Relative identifiers

The RID itself is computed in the following way:

Subtract the first POSIX ID of the range from the user's POSIX UID, and add the first RID of the corresponding RID range to the result. For example, if the UID of *idmuser* is 196600008, the first POSIX ID is 196600000, and the first RID is 1000, then *idmuser*'s RID is 1008.

NOTE

The algorithm computing the user's RID checks if a given POSIX ID falls into the ID range allocated before it computes a corresponding RID. For example, if the first ID is 196600000 and the range size is 200000, then the POSIX ID of 1600000 is outside of the ID range and the algorithm does not compute a RID for it.

Secondary relative identifiers

In IdM, a POSIX UID can be identical to a POSIX GID. This means that if *idmuser* already exists with the UID of 196600008, you can still create a new *idmgroup* group with the GID of 196600008.

However, a SID can define only one object, a user *or* a group. The SID of S-1-5-21-123-456-789-1008 that has already been created for *idmuser* cannot be shared with *idmgroup*. An alternative SID must be generated for *idmgroup*.

IdM uses a **secondary relative identifier**, or secondary RID, to avoid conflicting SIDs. This secondary RID consists of the following:

- The secondary RID base
- A range size; by default identical with the base range size

In the example above, the secondary RID base is set to 1000000. To compute the RID for the newly created *idmgroup*: subtract the first POSIX ID of the range from the user's POSIX UID, and add the first RID of the secondary RID range to the result. *idmgroup* is therefore assigned the RID of 1000008. Consequently, the SID of *idmgroup* is S-1-5-21-123-456-789-1000008.

IdM uses the secondary RID to compute a SID only if a user or a group object was previously created with a manually set POSIX ID. Otherwise, automatic assignment prevents assigning the same ID twice.

Additional resources

Using Ansible to add a new local IdM ID range

38.6. USING ANSIBLE TO ADD A NEW LOCAL IDM ID RANGE

In some cases, you may want to create a new Identity Management (IdM) ID range in addition to the original one; for example, when a replica has run out of IDs and the original IdM ID range is depleted. The following example describes how to create a new IdM ID range by using an Ansible playbook.

NOTE

Adding a new IdM ID range does not create new DNA ID ranges automatically. You need to assign new DNA ID ranges manually as needed. For more information about how to do this, see Assigning DNA ID ranges manually.

Prerequisites

- On the control node:
 - You are using Ansible version 2.15 or later.
 - You have installed the **freeipa.ansible_freeipa** collection.
 - The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.
 - The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin_password** and that you have access to a file that stores the password protecting the **secret.yml** file.
- The target node, that is the node on which the **freeipa.ansible_freeipa** module is executed, is part of the IdM domain as an IdM client, server or replica.

Procedure

1. Navigate to your ~/MyPlaybooks/ directory:

\$ cd ~/MyPlaybooks/

2. Create the **idrange-present.yml** playbook with the following content:

- name: Playbook to manage idrange

hosts: ipaserver become: no

vars_files:

- /home/user_name/MyPlaybooks/secret.yml

tasks:

- name: Ensure local idrange is present

ipaidrange:

ipaadmin password: "{{ ipaadmin password }}"

name: new_id_range base_id: 12000000 range_size: 200000 rid base: 1000000

secondary_rid_base: 200000000

3. Save the file.

4. Run the Ansible playbook. Specify the playbook file, the file storing the password protecting the **secret.yml** file, and the inventory file:

\$ ansible-playbook --vault-password-file=password_file -v -i inventory idrange-present.yml

5. **SSH** to **ipaserver** and restart the Directory Server:

systemctl restart dirsrv@IDM.EXAMPLE.COM.service

This ensures that when you create users with UIDs from the new range, they have security identifiers (SIDs) assigned.

- 6. Optional: Update the ID range immediately:
 - a. On **ipaserver**, clear the System Security Services Daemon (SSSD) cache:

sss_cache -E

b. On **ipaserver**, restart the SSSD daemon:

systemctl restart sssd

NOTE

If you do not clear the SSSD cache and restart the service, SSSD only detects the new ID range when it updates the domain list and other configuration data stored on the IdM server.

Verification

• You can check if the new range is set correctly by using the **ipa idrange-find** command:

ipa idrange-find

2 ranges matched

Range name: IDM.EXAMPLE.COM_id_range

First Posix ID of the range: 882200000 Number of IDs in the range: 200000 Range type: local domain range

Range name: IDM.EXAMPLE.COM new id range

First Posix ID of the range: 12000000 Number of IDs in the range: 200000 Range type: local domain range

Number of entries returned 2

Additional resources

• The role of security and relative identifiers in IdM ID ranges

38.7. REMOVING AN ID RANGE AFTER REMOVING A TRUST TO AD

If you have removed a trust between your Identity Management (IdM) and Active Directory (AD) environments, you might want to remove the ID range associated with it.

WARNING

IDs allocated to ID ranges associated with trusted domains might still be used for ownership of files and directories on systems enrolled into IdM.

If you remove the ID range that corresponds to an AD trust that you have removed, you will not be able to resolve the ownership of any files and directories owned by AD users

Prerequisites

• You have removed a trust to an AD environment.

Procedure

- 1. Display all the ID ranges that are currently in use:
 - [root@server ~]# ipa idrange-find
- 2. Identify the name of the ID range associated with the trust you have removed. The first part of the name of the ID range is the name of the trust, for example **AD.EXAMPLE.COM_id_range**.
- 3. Remove the range:
 - [root@server ~]# ipa idrange-del AD.EXAMPLE.COM_id_range
- 4. Restart the SSSD service to remove references to the ID range you have removed.
 - [root@server ~]# systemctl restart sssd

38.8. DISPLAYING CURRENTLY ASSIGNED DNA ID RANGES

You can display both the currently active Distributed Numeric Assignment (DNA) ID range on a server, as well as its next DNA range if it has one assigned.

Procedure

- To display which DNA ID ranges are configured for the servers in the topology, use the following commands:
 - **ipa-replica-manage dnarange-show** displays the current DNA ID range that is set on all servers or, if you specify a server, only on the specified server, for example:

ipa-replica-manage dnarange-show

serverA.example.com: 1001-1500 serverB.example.com: 1501-2000 serverC.example.com: No range set

ipa-replica-manage dnarange-show serverA.example.com

serverA.example.com: 1001-1500

• **ipa-replica-manage dnanextrange-show** displays the next DNA ID range currently set on all servers or, if you specify a server, only on the specified server, for example:

ipa-replica-manage dnanextrange-show

serverA.example.com: 2001-2500

serverB.example.com: No on-deck range set serverC.example.com: No on-deck range set

ipa-replica-manage dnanextrange-show server A. example.com

serverA.example.com: 2001-2500

38.9. MANUAL ID RANGE ASSIGNMENT

In certain situations, it is necessary to manually assign a Distributed Numeric Assignment (DNA) ID range, for example when:

A replica has run out of IDs and the IdM ID range is depleted
 A replica has exhausted the DNA ID range that was assigned to it, and requesting additional IDs failed because no more free IDs are available in the IdM range.

To solve this situation, extend the DNA ID range assigned to the replica. You can do this in two ways:

- Shorten the DNA ID range assigned to a different replica, then assign the newly available values to the depleted replica.
- Create a new IdM ID range, then set a new DNA ID range for the replica within this created IdM range.

For information about how to create a new IdM ID range, see Adding a new IdM ID range.

A replica stopped functioning

A replica's DNA ID range is not automatically retrieved when the replica stops functioning and must be deleted, which means the DNA ID range previously assigned to the replica becomes unavailable. You want to recover the DNA ID range and make it available for other replicas.

To do this, find out what the ID range values are , before manually assigning that range to a different server. Also, to avoid duplicate UIDs or GIDs, make sure that no ID value from the recovered range was previously assigned to a user or group; you can do this by examining the UIDs and GIDs of existing users and groups.

You can manually assign a DNA ID range to a replica using the commands in Assigning DNA ID ranges manually.

NOTE

If you assign a new DNA ID range, the UIDs of the already existing entries on the server or replica stay the same. This does not pose a problem because even if you change the current DNA ID range, IdM keeps a record of what ranges were assigned in the past.

38.10. ASSIGNING DNA ID RANGES MANUALLY

In some cases, you may need to manually assign Distributed Numeric Assignment (DNA) ID ranges to existing replicas, for example to reassign a DNA ID range assigned to a non-functioning replica. For more information, see Manual ID range assignment.

When adjusting a DNA ID range manually, make sure that the newly adjusted range is included in the IdM ID range; you can check this using the **ipa idrange-find** command. Otherwise, the command fails.

IMPORTANT

Be careful not to create overlapping ID ranges. If any of the ID ranges you assign to servers or replicas overlap, it could result in two different servers assigning the same ID value to different entries.

Prerequisites

• Optional: If you are recovering a DNA ID range from a non-functioning replica, first find the ID range using the commands described in Displaying currently assigned DNA ID ranges.

Procedure

- To define the current DNA ID range for a specified server, use ipa-replica-manage dnarangeset:
 - # ipa-replica-manage dnarange-set serverA.example.com 1250-1499
- To define the next DNA ID range for a specified server, use ipa-replica-manage dnanextrange-set:
 - # ipa-replica-manage dnanextrange-set serverB.example.com 1500-5000

Verification

 You can check that the new DNA ranges are set correctly by using the commands described in Displaying the currently assigned DNA ID ranges.

CHAPTER 39. MANAGING SUBID RANGES MANUALLY

In a containerized environment, sometimes an IdM user needs to assign subID ranges manually. The following instructions describe how to manage the subID ranges.

39.1. GENERATING SUBID RANGES USING IDM CLI

As an Identity Management (IdM) administrator, you can generate a subID range and assign it to IdM users.

Prerequisites

- The IdM users exist.
- You have obtained an IdM admin ticket-granting ticket (TGT). For details, see Using kinit to log in to IdM manually.
- You have **root** access to the IdM host where you are executing the procedure.

Procedure

1. Optional: Check for existing subID ranges:

ipa subid-find

- 2. If a subID range does not exist, select one of the following options:
 - Generate and assign a subID range to an IdM user:

ipa subid-generate --owner=idmuser

Added subordinate id "359dfcef-6b76-4911-bd37-bb5b66b8c418"

Unique ID: 359dfcef-6b76-4911-bd37-bb5b66b8c418

Description: auto-assigned subid

Owner: idmuser

SubUID range start: 2147483648

SubUID range size: 65536

SubGID range start: 2147483648 SubGID range size: 65536

• Generate and assign subID ranges to all IdM users:

/usr/libexec/ipa/ipa-subids --all-users

Found 2 user(s) without subordinate ids

Processing user 'user4' (1/2)

Processing user 'user5' (2/2)

Updated 2 user(s)

The ipa-subids command was successful

3. Optional: Assign subID ranges to new IdM users by default:

ipa config-mod --user-default-subid=True

Verification

• Verify that the user has a subID range assigned:

ipa subid-find --owner=idmuser

1 subordinate id matched

Unique ID: 359dfcef-6b76-4911-bd37-bb5b66b8c418

Owner: idmuser

SubUID range start: 2147483648

SubUID range size: 65536

SubGID range start: 2147483648

SubGID range size: 65536

Number of entries returned 1

39.2. GENERATING SUBID RANGES USING IDM WEBUI INTERFACE

As an Identity Management (IdM) administrator, you can generate a subID range and assign it to a user in the IdM WebUI interface.

Prerequisites

- The IdM user exists.
- You have obtained an IdM **admin** Kerberos ticket (TGT). See
- You have **root** access to the IdM host where you are executing the procedure.

Procedure

- 1. In the IdM WebUI interface expand the **Subordinate IDs** tab and choose the **Subordinate IDs** option.
- 2. When the **Subordinate IDs** interface appears, click the **Add** button in the upper-right corner of the interface. The **Add subid** window appears.
- 3. In the **Add subid** window choose an owner, that is the user to whom you want to assign a subID range.
- 4. Click the **Add** button.

Verification

• View the table under the **Subordinate IDs** tab. A new record shows in the table. The owner is the user to whom you assigned the subID range.

39.3. VIEWING SUBID INFORMATION ABOUT IDM USERS BY USING IDM CLI

As an Identity Management (IdM) user, you can search for IdM user subID ranges and view the related information.

Prerequisites

- You have configured a subID range on the IdM client. For more information, see Generating subID ranges using IdM CLI.
- You have obtained an IdM **admin** ticket-granting ticket (TGT). For details, see Using kinit to log in to IdM manually.

Procedure

- To view the details about a subID range:
 - If you know the unique ID hash of the Identity Management (IdM) user that is the owner of the range:

\$ ipa subid-show 359dfcef-6b76-4911-bd37-bb5b66b8c418

Unique ID: 359dfcef-6b76-4911-bd37-bb5b66b8c418

Owner: idmuser

SubUID range start: 2147483648 SubUID range size: 65536

SubGID range start: 2147483648 SubGID range size: 65536

• If you know a specific subID from that range:

\$ ipa subid-match --subuid=2147483670

1 subordinate id matched

Unique ID: 359dfcef-6b76-4911-bd37-bb5b66b8c418

Owner: uid=idmuser

SubUID range start: 2147483648

SubUID range size: 65536

SubGID range start: 2147483648 SubGID range size: 65536

Number of entries returned 1

39.4. LISTING SUBID RANGES USING THE GETSUBID COMMAND

As a system administrator, you can use the command line to list the subID ranges of Identity Management (IdM) or local users.

Prerequisites

- The **idmuser** user exists in IdM.
- The **shadow-utils-subid** package is installed.
- You can edit the /etc/nsswitch.conf file.

Procedure

Open the /etc/nsswitch.conf file and configure the shadow-utils utility to use IdM subID ranges by setting the subid variable to the sss value:

[...] subid: sss

NOTE

You can provide only one value for the **subid** field. Setting the **subid** field to the **file** value or no value instead of **sss** configures the **shadow-utils** utility to use the subID ranges from the **/etc/subuid** and **/etc/subgid** files.

2. List the subID range for an IdM user:

\$ getsubids idmuser

0: idmuser 2147483648 65536

The first value, 2147483648, indicates the subID range start. The second value, 65536, indicates the size of the range.

CHAPTER 40. MANAGING HOSTS IN IDM CLI

Learn about hosts and host entries in Identity Management (IdM), and the operations performed when managing hosts and host entries in IdM CLI.

40.1. HOSTS IN IDM

Identity Management (IdM) manages these identities:

- Users
- Services
- Hosts

A host represents a machine. As an IdM identity, a host has an entry in the IdM LDAP, that is the 389 Directory Server instance of the IdM server.

The host entry in IdM LDAP is used to establish relationships between other hosts and even services within the domain. These relationships are part of *delegating* authorization and control to hosts within the domain. Any host can be used in **host-based access control** (HBAC) rules.

IdM domain establishes a commonality between machines, with common identity information, common policies, and shared services. Any machine that belongs to a domain functions as a client of the domain, which means it uses the services that the domain provides. IdM domain provides three main services specifically for machines:

- DNS
- Kerberos
- Certificate management

Hosts in IdM are closely connected with the services running on them:

- Service entries are associated with a host.
- A host stores both the host and the service Kerberos principals.

40.2. HOST ENROLLMENT

This section describes enrolling hosts as IdM clients and what happens during and after the enrollment. The section compares the enrollment of IdM hosts and IdM users. The section also outlines alternative types of authentication available to hosts.

Enrolling a host consists of:

- Creating a host entry in IdM LDAP: possibly using the **ipa host-add** command in IdM CLI, or the equivalent IdM Web UI operation.
- Configuring IdM services on the host, for example the System Security Services Daemon (SSSD), Kerberos, and certmonger, and joining the host to the IdM domain.

The two actions can be performed separately or together.

If performed separately, they allow for dividing the two tasks between two users with different levels of privilege. This is useful for bulk deployments.

The **ipa-client-install** command can perform the two actions together. The command creates a host entry in IdM LDAP if that entry does not exist yet, and configures both the Kerberos and SSSD services for the host. The command brings the host within the IdM domain and allows it to identify the IdM server it will connect to. If the host belongs to a DNS zone managed by IdM, **ipa-client-install** adds DNS records for the host too. The command must be run on the client.

40.3. USER PRIVILEGES REQUIRED FOR HOST ENROLLMENT

The host enrollment operation requires authentication to prevent an unprivileged user from adding unwanted machines to the IdM domain. The privileges required depend on several factors, for example:

- If a host entry is created separately from running **ipa-client-install**
- If a one-time password (OTP) is used for enrollment

User privileges for optionally manually creating a host entry in IdM LDAP

The user privilege required for creating a host entry in IdM LDAP using the **ipa host-add** CLI command or the IdM Web UI is **Host Administrators**. The **Host Administrators** privilege can be obtained through the **IT Specialist** role.

User privileges for joining the client to the IdM domain

Hosts are configured as IdM clients during the execution of the **ipa-client-install** command. The level of credentials required for executing the **ipa-client-install** command depends on which of the following enrolling scenarios you find yourself in:

- The host entry in IdM LDAP does not exist. For this scenario, you need a full administrator's credentials or the **Host Administrators** role. A full administrator is a member of the **admins** group. The **Host Administrators** role provides privileges to add hosts and enroll hosts. For details about this scenario, see Installing a client using user credentials: interactive installation.
- The host entry in IdM LDAP exists. For this scenario, you need a limited administrator's credentials to execute **ipa-client-install** successfully. The limited administrator in this case has the **Enrollment Administrator** role, which provides the **Host Enrollment** privilege. For details, Installing a client using user credentials: interactive installation.
- The host entry in IdM LDAP exists, and an OTP has been generated for the host by a full or limited administrator. For this scenario, you can install an IdM client as an ordinary user if you run the **ipa-client-install** command with the **--password** option, supplying the correct OTP. For details, see Installing a client by using a one-time password: Interactive installation.

After enrollment, IdM hosts authenticate every new session to be able to access IdM resources. Machine authentication is required for the IdM server to trust the machine and to accept IdM connections from the client software installed on that machine. After authenticating the client, the IdM server can respond to its requests.

40.4. ENROLLMENT AND AUTHENTICATION OF IDM HOSTS AND USERS: COMPARISON

There are many similarities between users and hosts in IdM, some of which can be observed during the enrollment stage as well as those that concern authentication during the deployment stage.

- The enrollment stage (User and host enrollment):
 - An administrator can create an LDAP entry for both a user and a host before the user or host actually join IdM: for the stage user, the command is **ipa stageuser-add**; for the host, the command is **ipa host-add**.
- A file containing a *key table* or, abbreviated, keytab, a symmetric key resembling to some extent a user password, is created during the execution of the **ipa-client-install** command on the host, resulting in the host joining the IdM realm. Analogically, a user is asked to create a password when they activate their account, therefore joining the IdM realm.
- While the user password is the default authentication method for a user, the keytab is the default authentication method for a host. The keytab is stored in a file on the host.

Table 40.1. User and host enrollment

Action	User	Host
Pre-enrollment	\$ ipa stageuser-add user_name [- -password]	\$ ipa host-add host_name [random]
Activating the account	\$ ipa stageuser-activate user_name	\$ ipa-client install [password] (must be run on the host itself)

- The deployment stage (User and host session authentication):
- When a user starts a new session, the user authenticates using a password; similarly, every time it
 is switched on, the host authenticates by presenting its keytab file. The System Security
 Services Daemon (SSSD) manages this process in the background.
- If the authentication is successful, the user or host obtains a Kerberos ticket granting ticket (TGT).
- The TGT is then used to obtain specific tickets for specific services.

Table 40.2. User and host session authentication

	User	Host
Default means of authentication	Password	Keytabs
Starting a session (ordinary user)	\$ kinit user_name	[switch on the host]
The result of successful authentication	TGT to be used to obtain access to specific services	TGT to be used to obtain access to specific services

TGTs and other Kerberos tickets are generated as part of the Kerberos services and policies defined by the server. The initial granting of a Kerberos ticket, the renewing of the Kerberos credentials, and even the destroying of the Kerberos session are all handled automatically by the IdM services.

Alternative authentication options for IdM hosts

Apart from keytabs, IdM supports two other types of machine authentication:

- SSH keys. The SSH public key for the host is created and uploaded to the host entry. From there, the System Security Services Daemon (SSSD) uses IdM as an identity provider and can work in conjunction with OpenSSH and other services to reference the public keys located centrally in IdM.
- Machine certificates. In this case, the machine uses an SSL certificate that is issued by the IdM
 server's certificate authority and then stored in IdM's Directory Server. The certificate is then
 sent to the machine to present when it authenticates to the server. On the client, certificates are
 managed by a service called certmonger.

40.5. HOST OPERATIONS

The most common operations related to host enrollment and enablement, and the prerequisites, the context, and the consequences of performing those operations are outlined in the following sections.

Table 40.3. Host operations part 1

Action	What are the prerequisites of the action?	When does it make sense to run the command?	How is the action performed by a system administrator? What command(s) does he run?
Enrolling a client	see Preparing the system for Identity Management client installation in Installing Identity Manage ment	When you want the host to join the IdM realm.	Enrolling machines as clients in the IdM domain is a two-part process. A host entry is created for the client (and stored in the 389 Directory Server instance) when the ipa host-add command is run, and then a keytab is created to provision the client. Both parts are performed automatically by the ipa-client-install command. It is also possible to perform those steps separately; this allows for administrators to prepare machines and IdM in advance of actually configuring the clients. This allows more flexible setup scenarios, including bulk deployments.
Disabling a client	The host must have an entry in IdM. The host needs to have an active keytab.	When you want to remove the host from the IdM realm temporarily, perhaps for maintenance purposes.	ipa host-disable host_name

Action	What are the prerequisites of the action?	When does it make sense to run the command?	How is the action performed by a system administrator? What command(s) does he run?
Enabling a client	The host must have an entry in IdM.	When you want the temporarily disabled host to become active again.	ipa-getkeytab
Re-enrolling a client	The host must have en entry in IdM.	When the original host has been lost but you have installed a host with the same host name.	ipa-client-installkeytab or ipa-client-installforce-join
Un-enrolling a client	The host must have an entry in IdM.	When you want to remove the host from the IdM realm permanently.	ipa-client-installuninstall

Table 40.4. Host operations part 2

Action	On which machine can the administrator run the command(s)?	What happens when the action is performed? What are the consequences for the host's functioning in IdM? What limitations are introduced/removed?
Enrolling a client	In the case of a two-step enrollment: ipa host-add can be run on any IdM client; the second step of ipa-client-install must be run on the client itself	By default this configures SSSD to connect to an IdM server for authentication and authorization. Optionally one can instead configure the Pluggable Authentication Module (PAM) and the Name Switching Service (NSS) to work with an IdM server over Kerberos and LDAP.
Disabling a client	Any machine in IdM, even the host itself	The host's Kerberos key and SSL certificate are invalidated, and all services running on the host are disabled.

Action	On which machine can the administrator run the command(s)?	What happens when the action is performed? What are the consequences for the host's functioning in IdM? What limitations are introduced/removed?
Enabling a client	Any machine in IdM. If run on the disabled host, LDAP credentials need to be supplied.	The host's Kerberos key and the SSL certificate are made valid again, and all IdM services running on the host are re-enabled.
Re-enrolling a client	The host to be reenrolled. LDAP credentials need to be supplied.	A new Kerberos key is generated for the host, replacing the previous one.
Un-enrolling a client	The host to be unenrolled.	The command unconfigures IdM and attempts to return the machine to its previous state. Part of this process is to unenroll the host from the IdM server. Unenrollment consists of disabling the principal key on the IdM server. The machine principal in /etc/krb5.keytab (host/ <fqdn>@REALM) is used to authenticate to the IdM server to unenroll itself. If this principal does not exist then unenrollment will fail and an administrator will need to disable the host principal (ipa host-disable <fqdn>).</fqdn></fqdn>

40.6. HOST ENTRY IN IDM LDAP

An Identity Management (IdM) host entry contains information about the host and what attributes it can contain.

An LDAP host entry contains all relevant information about the client within IdM:

- Service entries associated with the host
- The host and service principal
- Access control rules
- Machine information, such as its physical location and operating system

NOTE

Note that the IdM Web UI **Identity** \rightarrow **Hosts** tab does not show all the information about a particular host stored in the IdM LDAP.

Host entry configuration properties

A host entry can contain information about the host that is outside its system configuration, such as its physical location, MAC address, keys, and certificates.

This information can be set when the host entry is created if it is created manually. Alternatively, most of this information can be added to the host entry after the host is enrolled in the domain.

Table 40.5. Host Configuration Properties

UI Field	Command-Line Option	Description
Description	desc=description	A description of the host.
Locality	locality=locality	The geographic location of the host.
Location	location=location	The physical location of the host, such as its data center rack.
Platform	platform=string	The host hardware or architecture.
Operating system	os =string	The operating system and version for the host.
MAC address	macaddress=address	The MAC address for the host. This is a multi-valued attribute. The MAC address is used by the NIS plug-in to create a NIS ethers map for the host.
SSH public keys	sshpubkey=string	The full SSH public key for the host. This is a multi-valued attribute, so multiple keys can be set.
Principal name (not editable)	principalname=principal	The Kerberos principal name for the host. This defaults to the host name during the client installation, unless a different principal is explicitly set in the -p . This can be changed using the command-line tools, but cannot be changed in the UI.
Set One-Time Password	password=string	This option sets a password for the host which can be used in bulk enrollment.
-	random	This option generates a random password to be used in bulk enrollment.
-	certificate=string	A certificate blob for the host.

UI Field	Command-Line Option	Description
-	updatedns	This sets whether the host can dynamically update its DNS entries if its IP address changes.

40.7. ADDING IDM HOST ENTRIES FROM IDM CLI

Follow this procedure to add host entries in Identity Management (IdM) using the command line (CLI).

Host entries are created using the **host-add** command. This commands adds the host entry to the IdM Directory Server. Consult the **ipa host** manpage by typing **ipa help host** in your CLI to get the full list of options available with **host-add**.

There are a few different scenarios when adding a host to IdM:

- At its most basic, specify only the client host name to add the client to the Kerberos realm and to create an entry in the IdM LDAP server:
 - \$ ipa host-add client1.example.com
- If the IdM server is configured to manage DNS, add the host to the DNS resource records using the **--ip-address** option to create a host entry with static IP address.
 - \$ ipa host-add --ip-address=192.168.166.31 client1.example.com
- If the host to be added does not have a static IP address or if the IP address is not known at the time the client is configured, use the **--force** option with the **ipa host-add** command to create a host entry with DHCP.
 - \$ ipa host-add --force client1.example.com

For example, laptops may be preconfigured as IdM clients, but they do not have IP addresses at the time they are configured. Using **--force** essentially creates a placeholder entry in the IdM DNS service. When the DNS service dynamically updates its records, the host's current IP address is detected and its DNS record is updated.

40.8. DELETING HOST ENTRIES FROM IDM CLI

Use the **host-del** command to delete host records. If your IdM domain has integrated DNS, use the **--updatedns** option to remove the associated records of any kind for the host from the DNS:

\$ ipa host-del --updatedns client1.example.com

40.9. DISABLING AND RE-ENABLING HOST ENTRIES

This section describes how to disable and re-enable hosts in Identity Management (IdM).

40.9.1. Disabling Hosts

Complete this procedure to disable a host entry in IdM.

Domain services, hosts, and users can access an active host. There can be situations when it is necessary to remove an active host temporarily, for maintenance reasons, for example. Deleting the host in such situations is not desired as it removes the host entry and all the associated configuration permanently. Instead, choose the option of disabling the host.

Disabling a host prevents domain users from accessing it without permanently removing it from the domain.

Procedure

• Disable a host using the **host-disable** command. Disabling a host kills the host's current, active keytabs. For example:

\$ kinit admin \$ ipa host-disable client.example.com

As a result of disabling a host, the host becomes unavailable to all IdM users, hosts and services.

IMPORTANT

Disabling a host entry not only disables that host. It disables every configured service on that host as well.

40.9.2. Re-enabling Hosts

Follow this procedure to re-enable a disabled IdM host.

Disabling a host killed its active keytabs, which removed the host from the IdM domain without otherwise touching its configuration entry.

Procedure

- To re-enable a host, use the **ipa-getkeytab** command, adding:
 - the **-s** option to specify which IdM server to request the keytab from
 - the **-p** option to specify the principal name
 - the **-k** option to specify the file to which to save the keytab.

For example, to request a new host keytab from **server.example.com** for **client.example.com**, and store the keytab in the /**etc/krb5.keytab** file:

\$ ipa-getkeytab -s server.example.com -p host/client.example.com -k /etc/krb5.keytab -D "cn=directory manager" -w password

NOTE

You can also use the administrator's credentials, specifying **-D** "uid=admin,cn=users,cn=accounts,dc=example,dc=com". It is important that the credentials correspond to a user allowed to create the keytab for the host.

If the **ipa-getkeytab** command is run on an active IdM client or server, then it can be run without any LDAP credentials (**-D** and **-w**) if the user has a TGT obtained using, for example, **kinit admin**. To run the command directly on the disabled host, supply LDAP credentials to authenticate to the IdM server.

40.10. DELEGATING ACCESS TO HOSTS AND SERVICES

By delegating access to hosts and services within an IdM domain, you can retrieve keytabs and certificates for another host or service.

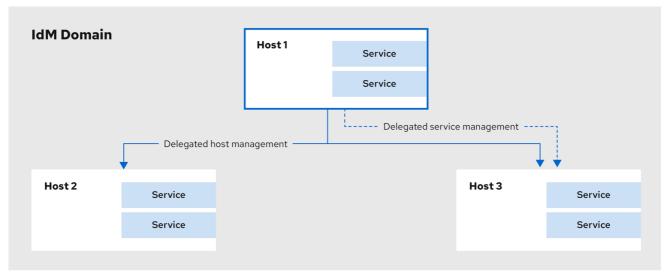

Each host and service has a **managedby** entry that lists what hosts and services can manage it. By default, a host can manage itself and all of its services. You can configure a host to manage other hosts, or services on other hosts within the IdM domain.

NOTE

When you delegate authority of a host to another host through a **managedby** entry, it does not automatically grant management rights for all services on that host. You must perform each delegation independently.

Host and service delegation

640 RHFI 0424

40.10.1. Delegating service management

You can delegate permissions to a host to manage a service on another host within the domain.

When you delegate permissions to a host to manage another host, it does not automatically include permissions to manage its services. You must delegate service management independently.

Procedure

 Delegate the management of a service to a specific host by using the **service-add-host** command:

ipa service-add-host principal --hosts=<hostname>

You must specify the service principal using the **principal** argument and the hosts with control using the **--hosts** option.

For example:

[root@server ~]# ipa service-add HTTP/web.example.com [root@server ~]# ipa service-add-host HTTP/web.example.com -hosts=client1.example.com

2. Once the host is delegated authority, the host principal can be used to manage the service:

[root@client1 ~]# kinit -kt /etc/krb5.keytab host/client1.example.com [root@client1 ~]# ipa-getkeytab -s server.example.com -k /tmp/test.keytab -p HTTP/web.example.com Keytab successfully retrieved and stored in: /tmp/test.keytab

3. To generate a certificate for the delegated service, create a certificate request on the host with the delegated authority:

```
[root@client1]# kinit -kt /etc/krb5.keytab host/client1.example.com
[root@client1]# openssl req -newkey rsa:2048 -subj
'/CN=web.example.com/O=EXAMPLE.COM' -keyout /etc/pki/tls/web.key -out
/tmp/web.csr -nodes
Generating a 2048 bit RSA private key
.....+++
Writing new private key to '/etc/pki/tls/private/web.key'
```

4. Use the **cert-request** utility to submit the certificate request and load the certification information:

[root@client1]# ipa cert-request --principal=HTTP/web.example.com web.csr

Certificate: MIICETCCAXqgA...[snip]

Subject: CN=web.example.com,O=EXAMPLE.COM Issuer: CN=EXAMPLE.COM Certificate Authority Not Before: Tue Feb 08 18:51:51 2011 UTC Not After: Mon Feb 08 18:51:51 2016 UTC

Serial number: 1005

Additional resources

Managing certificates for users, hosts, and services using the integrated IdM CA

40.10.2. Delegating host management

You can delegate authority for a host to manage another host by using the **host-add-managedby** utility. This creates a **managedby** entry. After the **managedby** entry is created, the managing host can retrieve a keytab for the host it manages.

Procedure

1. Log in as the admin user:

[root@server ~]# kinit admin

2. Add the **managedby** entry. For example, this delegates authority over *client2* to *client1*:

[root@server ~]# ipa host-add-managedby client2.example.com -- hosts=client1.example.com

3. Obtain a ticket as the host client1:

[root@client1 ~]# kinit -kt /etc/krb5.keytab host/client1.example.com

4. Retrieve a keytab for client2:

[root@client1 ~]# ipa-getkeytab -s server.example.com -k /tmp/client2.keytab -p host/client2.example.com

Keytab successfully retrieved and stored in: /tmp/client2.keytab

40.10.3. Accessing delegated services

When a client has delegated authority, it can obtain a keytab for the principal on the local machine for both services and hosts.

With the **kinit** command, use the **-k** option to load a keytab and the **-t** option to specify the keytab. The principal format is **<pri>rincipal>/hostname@REALM**. For a service, replace **<principal>** with the service name, for example HTTP. For a host, use **host** as the principal.

Procedure

• To access a host:

[root@server ~]# kinit -kt /etc/krb5.keytab host/ipa.example.com@EXAMPLE.COM

• To access a service:

[root@server ~]# kinit -kt /etc/httpd/conf/krb5.keytab HTTP/ipa.example.com@EXAMPLE.COM

40.11. ADDITIONAL RESOURCES

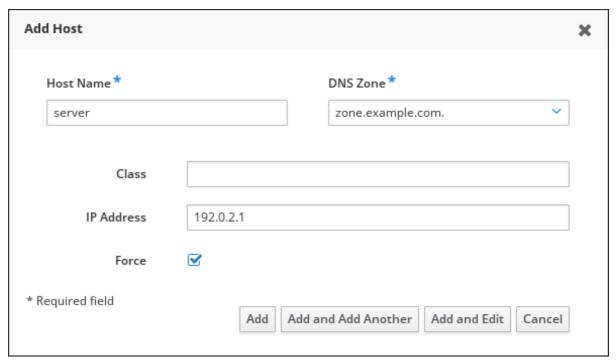

- Re-enrolling an IdM client
- Renaming IdM client systems

CHAPTER 41. ADDING HOST ENTRIES FROM THE WEB UI

- 1. Open the **Identity** tab, and select the **Hosts** subtab.
- 2. Click **Add** at the top of the hosts list.
- 3. Enter the machine name and select the domain from the configured zones in the drop-down list. If the host has already been assigned a static IP address, then include that with the host entry so that the DNS entry is fully created.

The **Class** field has no specific purpose at the moment.

Figure 41.1. Add Host Wizard

DNS zones can be created in IdM. If the IdM server does not manage the DNS server, the zone can be entered manually in the menu area, like a regular text field.

NOTE

Select the **Force** checkbox if you want to skip checking whether the host is resolvable via DNS.

4. Click the **Add and Edit** button to go directly to the expanded entry page and enter more attribute information. Information about the host hardware and physical location can be included with the host entry.

Additional resources

- Hosts in IdM
- Host enrollment
- User privileges required for host enrollment

- Host Operations
- Host entry in IdM LDAP

CHAPTER 42. MANAGING HOSTS USING ANSIBLE PLAYBOOKS

Ansible is an automation tool used to configure systems, deploy software, and perform rolling updates. Ansible includes support for Identity Management (IdM), and you can use Ansible modules to automate host management.

42.1. ENSURING THE PRESENCE OF AN IDM HOST ENTRY WITH FQDN USING ANSIBLE PLAYBOOKS

Follow this procedure to ensure the presence of host entries in Identity Management (IdM) using Ansible playbooks. The host entries are only defined by their **fully-qualified domain names** (FQDNs).

Specifying the **FQDN** name of the host is enough if at least one of the following conditions applies:

- The IdM server is not configured to manage DNS.
- The host does not have a static IP address or the IP address is not known at the time the host is configured. Adding a host defined only by an **FQDN** essentially creates a placeholder entry in the IdM DNS service. For example, laptops may be preconfigured as IdM clients, but they do not have IP addresses at the time they are configured. When the DNS service dynamically updates its records, the host's current IP address is detected and its DNS record is updated.

NOTE

Without Ansible, host entries are created in IdM using the **ipa host-add** command. The result of adding a host to IdM is the state of the host being present in IdM. Because of the Ansible reliance on idempotence, to add a host to IdM using Ansible, you must create a playbook in which you define the state of the host as present: **state:** present.

Prerequisites

- You have configured your Ansible control node to meet the following requirements:
 - You are using Ansible version 2.15 or later.
 - You have installed the **freeipa.ansible_freeipa** collection.
 - The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.
 - The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin_password** and that you have access to a file that stores the password protecting the **secret.yml** file.
- The target node, that is the node on which the freeipa.ansible_freeipa module is executed, is part of the IdM domain as an IdM client, server or replica.

Procedure

 Create an Ansible playbook file with the FQDN of the host whose presence in IdM you want to ensure. To simplify this step, you can copy and modify the example in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/host/ add-host.yml file: ---

 name: Host present hosts: ipaserver

vars files:

- /home/user_name/MyPlaybooks/secret.yml

name: Host host01.idm.example.com present {ipahost}:

ipaadmin_password: "{{ ipaadmin_password }}"

name: host01.idm.example.com

state: present force: true

2. Run the playbook:

\$ ansible-playbook --vault-password-file=password_file -v -i path_to_inventory_directory/inventory.file path_to_playbooks_directory/ensure-host-is-present.yml

NOTE

The procedure results in a host entry in the IdM LDAP server being created but not in enrolling the host into the IdM Kerberos realm. For that, you must deploy the host as an IdM client. For details, see Installing an Identity Management client using an Ansible playbook.

Verification

1. Log in to your IdM server as **admin**:

\$ ssh admin@server.idm.example.com Password:

2. Enter the **ipa host-show** command and specify the name of the host:

\$ ipa host-show host01.idm.example.com

Host name: host01.idm.example.com

Principal name: host/host01.idm.example.com@IDM.EXAMPLE.COM Principal alias: host/host01.idm.example.com@IDM.EXAMPLE.COM

Password: False Keytab: False

Managed by: host01.idm.example.com

The output confirms that **hostO1.idm.example.com** exists in IdM.

42.2. ENSURING THE PRESENCE OF AN IDM HOST ENTRY WITH DNS INFORMATION USING ANSIBLE PLAYBOOKS

Follow this procedure to ensure the presence of host entries in Identity Management (IdM) using Ansible playbooks. The host entries are defined by their **fully-qualified domain names** (FQDNs) and their IP addresses.

NOTE

Without Ansible, host entries are created in IdM using the **ipa host-add** command. The result of adding a host to IdM is the state of the host being present in IdM. Because of the Ansible reliance on idempotence, to add a host to IdM using Ansible, you must create a playbook in which you define the state of the host as present: **state: present**.

Prerequisites

- You know the IdM administrator password.
- You have configured your Ansible control node to meet the following requirements:
 - You are using Ansible version 2.15 or later.
 - You have installed the **freeipa.ansible_freeipa** collection.
 - The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.
 - The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin_password** and that you have access to a file that stores the password protecting the **secret.yml** file.
- The target node, that is the node on which the freeipa.ansible_freeipa module is executed, is part of the IdM domain as an IdM client, server or replica.

Procedure

1. Create an Ansible playbook file with the **fully-qualified domain name** (FQDN) of the host whose presence in IdM you want to ensure. In addition, if the IdM server is configured to manage DNS and you know the IP address of the host, specify a value for the **ip_address** parameter. The IP address is necessary for the host to exist in the DNS resource records. To simplify this step, you can copy and modify the example in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/host/host-present.yml file. You can also include other, additional information:

 name: Host present hosts: ipaserver

vars files:

- /home/user_name/MyPlaybooks/secret.yml tasks:

name: Ensure host01.idm.example.com is present {ipahost}:

ipaadmin_password: "{{ ipaadmin_password }}"

name: host01.idm.example.com description: Example host ip_address: 192.168.0.123

locality: Lab

ns_host_location: Lab ns_os_version: CentOS 7

ns_hardware_platform: Lenovo T61

mac_address:

- "08:00:27:E3:B1:2D" - "52:54:00:BD:97:1E" state: present

2. Run the playbook:

\$ ansible-playbook --vault-password-file=password_file -v -i path_to_inventory_directory/inventory.file path_to_playbooks_directory/ensure-host-is-present.yml

NOTE

The procedure results in a host entry in the IdM LDAP server being created but not in enrolling the host into the IdM Kerberos realm. For that, you must deploy the host as an IdM client. For details, see Installing an Identity Management client using an Ansible playbook.

Verification

1. Log in to your IdM server as admin:

\$ ssh admin@server.idm.example.com Password:

2. Enter the **ipa host-show** command and specify the name of the host:

\$ ipa host-show host01.idm.example.com

Host name: host01.idm.example.com

Description: Example host

Locality: Lab Location: Lab

Platform: Lenovo T61

Operating system: CentOS 7

Principal name: host/host01.idm.example.com@IDM.EXAMPLE.COM Principal alias: host/host01.idm.example.com@IDM.EXAMPLE.COM

MAC address: 08:00:27:E3:B1:2D, 52:54:00:BD:97:1E

Password: False Keytab: False

Managed by: host01.idm.example.com

The output confirms **hostO1.idm.example.com** exists in IdM.

42.3. ENSURING THE PRESENCE OF MULTIPLE IDM HOST ENTRIES WITH RANDOM PASSWORDS USING ANSIBLE PLAYBOOKS

The **{ipahost}** module allows the system administrator to ensure the presence or absence of multiple host entries in IdM using just one Ansible task. Follow this procedure to ensure the presence of multiple host entries that are only defined by their **fully-qualified domain names** (FQDNs). Running the Ansible playbook generates random passwords for the hosts.

NOTE

Without Ansible, host entries are created in IdM using the **ipa host-add** command. The result of adding a host to IdM is the state of the host being present in IdM. Because of the Ansible reliance on idempotence, to add a host to IdM using Ansible, you must create a playbook in which you define the state of the host as present: **state:** present.

Prerequisites

- You have configured your Ansible control node to meet the following requirements:
 - You are using Ansible version 2.15 or later.
 - You have installed the **freeipa.ansible_freeipa** collection.
 - The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.
 - The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin_password** and that you have access to a file that stores the password protecting the **secret.yml** file.
- The target node, that is the node on which the **freeipa.ansible_freeipa** module is executed, is part of the IdM domain as an IdM client, server or replica.

Procedure

 Create an Ansible playbook file with the fully-qualified domain name (FQDN) of the hosts whose presence in IdM you want to ensure. To make the Ansible playbook generate a random password for each host even when the host already exists in IdM and update_password is limited to on_create, add the random: true and force: true options. To simplify this step, you can copy and modify the example from the

/usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/README-host.md Markdown file:

- name: Ensure hosts with random password

hosts: ipaserver

vars files:

 $\hbox{- /home/user_name/MyPlaybooks/secret.yml}$

tasks:

- name: Hosts host01.idm.example.com and host02.idm.example.com present with random passwords

{ipahost}:

ipaadmin_password: "{{ ipaadmin_password }}"

hosts:

- name: host01.idm.example.com

random: true force: true

- name: host02.idm.example.com

random: true force: true register: ipahost

2. Run the playbook:

\$ ansible-playbook --vault-password-file=password_file -v -i path_to_inventory_directory/inventory.file path_to_playbooks_directory/ensure-hostsare-present.yml

[...]

TASK [Hosts host01.idm.example.com and host02.idm.example.com present with random passwords]

changed: [r8server.idm.example.com] => {"changed": true, "host":

 $\\ \{ "host 01. idm. example.com" : \{ "random password" : "0HoIRvjUdH0Ycbf6uYdWTxH" \}, \\$

"host02.idm.example.com": {"randompassword": "5VdLgrf3wvojmACdHC3uA3s"}}}

NOTE

To deploy the hosts as IdM clients using random, one-time passwords (OTPs), see Authorization options for IdM client enrollment using an Ansible playbook or Installing a client by using a one-time password: Interactive installation.

Verification

1. Log in to your IdM server as admin:

\$ ssh admin@server.idm.example.com Password:

2. Enter the **ipa host-show** command and specify the name of one of the hosts:

\$ ipa host-show host01.idm.example.com

Host name: host01.idm.example.com

Password: True Keytab: False

Managed by: host01.idm.example.com

The output confirms **hostO1.idm.example.com** exists in IdM with a random password.

42.4. ENSURING THE PRESENCE OF AN IDM HOST ENTRY WITH MULTIPLE IP ADDRESSES USING ANSIBLE PLAYBOOKS

Follow this procedure to ensure the presence of a host entry in Identity Management (IdM) using Ansible playbooks. The host entry is defined by its **fully-qualified domain name** (FQDN) and its multiple IP addresses.

NOTE

In contrast to the **ipa host** utility, the Ansible **{ipahost}** module can ensure the presence or absence of several IPv4 and IPv6 addresses for a host. The **ipa host-mod** command cannot handle IP addresses.

Prerequisites

- You have configured your Ansible control node to meet the following requirements:
 - You are using Ansible version 2.15 or later.
 - You have installed the freeipa.ansible_freeipa collection.

- The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.
- The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin_password** and that you have access to a file that stores the password protecting the **secret.yml** file.
- The target node, that is the node on which the **freeipa.ansible_freeipa** module is executed, is part of the IdM domain as an IdM client, server or replica.

Procedure

1. Create an Ansible playbook file. Specify, as the name of the {ipahost} variable, the fully-qualified domain name (FQDN) of the host whose presence in IdM you want to ensure. Specify each of the multiple IPv4 and IPv6 ip_address values on a separate line by using the ip_address syntax. To simplify this step, you can copy and modify the example in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/host/host-member-ipaddresses-present.yml file. You can also include additional information:

- name: Host member IP addresses present

hosts: ipaserver

vars files:

- /home/user_name/MyPlaybooks/secret.yml

tasks

- name: Ensure host101.example.com IP addresses present {ipahost}:

ipaadmin_password: "{{ ipaadmin_password }}"

name: host01.idm.example.com

ip address:

- 192.168.0.123

- fe80::20c:29ff:fe02:a1b3

- 192.168.0.124

- fe80::20c:29ff:fe02:a1b4

force: true

2. Run the playbook:

\$ ansible-playbook --vault-password-file=password_file -v -i path_to_inventory_directory/inventory.file path_to_playbooks_directory/ensure-host-with-multiple-IP-addreses-is-present.yml

NOTE

The procedure creates a host entry in the IdM LDAP server but does not enroll the host into the IdM Kerberos realm. For that, you must deploy the host as an IdM client. For details, see Installing an Identity Management client using an Ansible playbook.

Verification

1. Log in to your IdM server as admin:

\$ ssh admin@server.idm.example.com Password: 2. Enter the **ipa host-show** command and specify the name of the host:

\$ ipa host-show host01.idm.example.com

Principal name: host/host01.idm.example.com@IDM.EXAMPLE.COM Principal alias: host/host01.idm.example.com@IDM.EXAMPLE.COM

Password: False Keytab: False

Managed by: host01.idm.example.com

The output confirms that host01.idm.example.com exists in IdM.

3. To verify that the multiple IP addresses of the host exist in the IdM DNS records, enter the **ipa dnsrecord-show** command and specify the following information:

• The name of the IdM domain

• The name of the host

\$ ipa dnsrecord-show idm.example.com host01

[...]

Record name: host01

A record: 192.168.0.123, 192.168.0.124

AAAA record: fe80::20c:29ff:fe02:a1b3, fe80::20c:29ff:fe02:a1b4

The output confirms that all the IPv4 and IPv6 addresses specified in the playbook are correctly associated with the **host01.idm.example.com** host entry.

42.5. ENSURING THE ABSENCE OF AN IDM HOST ENTRY USING ANSIBLE PLAYBOOKS

Follow this procedure to ensure the absence of host entries in Identity Management (IdM) using Ansible playbooks.

Prerequisites

- You have configured your Ansible control node to meet the following requirements:
 - You are using Ansible version 2.15 or later.
 - You have installed the **freeipa.ansible_freeipa** collection.
 - The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.
 - The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin_password** and that you have access to a file that stores the password protecting the **secret.yml** file.
- The target node, that is the node on which the **freeipa.ansible_freeipa** module is executed, is part of the IdM domain as an IdM client, server or replica.

Procedure

 Create an Ansible playbook file with the fully-qualified domain name (FQDN) of the host whose absence from IdM you want to ensure. If your IdM domain has integrated DNS, use the updatedns: true option to remove the associated records of any kind for the host from the DNS.

To simplify this step, you can copy and modify the example in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/host/delete-host.yml file:

 name: Host absent hosts: ipaserver

vars files:

- /home/user_name/MyPlaybooks/secret.yml tasks:

name: Host host01.idm.example.com absent {ipahost}:

ipaadmin_password: "{{ ipaadmin_password }}"

name: host01.idm.example.com

updatedns: true state: absent

2. Run the playbook:

\$ ansible-playbook --vault-password-file=password_file -v -i path_to_inventory_directory/inventory.file path_to_playbooks_directory/ensure-host-absent.yml

NOTE

The procedure results in:

- The host not being present in the IdM Kerberos realm.
- The host entry not being present in the IdM LDAP server.

To remove the specific IdM configuration of system services, such as System Security Services Daemon (SSSD), from the client host itself, you must run the **ipa-client-install -- uninstall** command on the client. For details, see Uninstalling an IdM client.

Verification

1. Log into **ipaserver** as admin:

\$ ssh admin@server.idm.example.com Password: [admin@server /]\$

2. Display information about host01.idm.example.com:

\$ ipa host-show host01.idm.example.com ipa: ERROR: host01.idm.example.com: host not found

The output confirms that the host does not exist in IdM.

Additional resources

- See the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/README-host.md Markdown file.
- See the additional playbooks in the /usr/share/ansible/collections/ansible_collections/freeipa/ansible_freeipa/playbooks/host directory.

CHAPTER 43. MANAGING HOST GROUPS USING THE IDM CLI

Learn more about how to manage host groups and their members on the command line (CLI) by using the following operations:

- Viewing host groups and their members
- Creating host groups
- Deleting host groups
- Adding host group members
- Removing host group members
- Adding host group member managers
- Removing host group member managers

43.1. HOST GROUPS IN IDM

IdM host groups can be used to centralize control over important management tasks, particularly access control.

Definition of host groups

A host group is an entity that contains a set of IdM hosts with common access control rules and other characteristics. For example, you can define host groups based on company departments, physical locations, or access control requirements.

A host group in IdM can include:

- IdM servers and clients
- Other IdM host groups

Host groups created by default

By default, the IdM server creates the host group ipaservers for all IdM server hosts.

Direct and indirect group members

Group attributes in IdM apply to both direct and indirect members: when host group B is a member of host group A, all members of host group B are considered indirect members of host group A.

43.2. VIEWING IDM HOST GROUPS USING THE CLI

Follow this procedure to view IdM host groups using the command line (CLI).

Prerequisites

- Administrator privileges for managing IdM or User Administrator role.
- An active Kerberos ticket. For details, see Using kinit to log in to IdM manually.

1. Find all host groups using the **ipa hostgroup-find** command.

\$ ipa hostgroup-find ----- 1 hostgroup matched ----- Host-group: ipaservers Description: IPA server hosts ----- Number of entries returned 1

2. To display all attributes of a host group, add the **--all** option. For example:

43.3. CREATING IDM HOST GROUPS USING THE CLI

Follow this procedure to create IdM host groups using the command line (CLI).

Prerequisites

- Administrator privileges for managing IdM or User Administrator role.
- An active Kerberos ticket. For details, see Using kinit to log in to IdM manually .

Procedure

Add a host group using the ipa hostgroup-add command.
 For example, to create an IdM host group named group_name and give it a description:

43.4. DELETING IDM HOST GROUPS USING THE CLI

Follow this procedure to delete IdM host groups using the command line (CLI).

Prerequisites

- Administrator privileges for managing IdM or User Administrator role.
- An active Kerberos ticket. For details, see Using kinit to log in to IdM manually.

Procedure

• Delete a host group using the **ipa hostgroup-del** command. For example, to delete the IdM host group named *group_name*:

```
$ ipa hostgroup-del group_name
-----
Deleted hostgroup "group_name"
------
```

NOTE

Removing a group does not delete the group members from IdM.

43.5. ADDING IDM HOST GROUP MEMBERS USING THE CLI

You can add hosts as well as host groups as members to an IdM host group using a single command.

Prerequisites

- Administrator privileges for managing IdM or User Administrator role.
- An active Kerberos ticket. For details, see Using kinit to log in to IdM manually.
- Optional: Use the **ipa hostgroup-find** command to find hosts and host groups.

Procedure

- To add a member to a host group, use the **ipa hostgroup-add-member** command and provide the relevant information. You can specify the type of member to add using these options:
 - Use the **--hosts** option to add one or more hosts to an IdM host group. For example, to add the host named *example_member* to the group named *group_name*:

```
$ ipa hostgroup-add-member group_name --hosts example_member

Host-group: group_name

Description: My host group

Member hosts: example_member

------

Number of members added 1

-------
```

• Use the **--hostgroups** option to add one or more host groups to an IdM host group. For example, to add the host group named *nested_group* to the group named *group_name*:

\$ ipa hostgroup-add-member group_name --hostgroups nested_group

Host-group: group_name Description: My host group

Member host-groups: nested_group

Number of members added 1

• You can add multiple hosts and multiple host groups to an IdM host group in one single command using the following syntax:

\$ ipa hostgroup-add-member *group_name* --hosts={host1,host2} --hostgroups= {group1,group2}

IMPORTANT

When adding a host group as a member of another host group, do not create recursive groups. For example, if Group A is a member of Group B, do not add Group B as a member of Group A. Recursive groups can cause unpredictable behavior.

43.6. REMOVING IDM HOST GROUP MEMBERS USING THE CLI

You can remove hosts as well as host groups from an IdM host group using a single command.

Prerequisites

- Administrator privileges for managing IdM or User Administrator role.
- An active Kerberos ticket. For details, see Using kinit to log in to IdM manually .
- Optional. Use the **ipa hostgroup-find** command to confirm that the group includes the member you want to remove.

Procedure

- To remove a host group member, use the **ipa hostgroup-remove-member** command and provide the relevant information. You can specify the type of member to remove using these options:
 - Use the --hosts option to remove one or more hosts from an IdM host group.
 For example, to remove the host named example_member from the group named group_name:

\$ ipa hostgroup-remove-member group_name --hosts example_member
Host-group: group_name
Description: My host group
-----Number of members removed 1

Use the --hostgroups option to remove one or more host groups from an IdM host group.
 For example, to remove the host group named nested_group from the group named group_name:

\$ ipa hostgroup-remove-member group_name --hostgroups example_member

Host-group: group_name Description: My host group

Number of members removed 1

NOTE

Removing a group does not delete the group members from IdM.

• You can remove multiple hosts and multiple host groups from an IdM host group in one single command using the following syntax:

\$ ipa hostgroup-remove-member group_name --hosts={host1,host2} --hostgroups={group1,group2}

43.7. ADDING IDM HOST GROUP MEMBER MANAGERS USING THE CLI

You can add hosts as well as host groups as member managers to an IdM host group using a single command. Member managers can add hosts or host groups to IdM host groups but cannot change the attributes of a host group.

Prerequisites

- Administrator privileges for managing IdM or User Administrator role.
- An active Kerberos ticket. For details, see Using kinit to log in to IdM manually .
- You must have the name of the host or host group you are adding as member managers and the name of the host group you want them to manage.

Procedure

- 1. Optional: Use the **ipa hostgroup-find** command to find hosts and host groups.
- 2. To add a member manager to a host group, use the **ipa hostgroup-add-member-manager**. For example, to add the user named *example_member* as a member manager to the group named *group_name*:

\$ ipa hostgroup-add-member-manager group_name --user example_member

Host-group: group_name

Member hosts: server.idm.example.com Member host-groups: project_admins Member of netgroups: group_name

Membership managed by users: example_member

Number of members added 1

3. Use the **--groups** option to add one or more host groups as a member manager to an IdM host group.

For example, to add the host group named *admin_group* as a member manager to the group named *group_name*:

\$ ipa hostgroup-add-member-manager group_name --groups admin_group

Host-group: group_name

Member hosts: server.idm.example.com Member host-groups: project_admins Member of netgroups: group_name

Membership managed by groups: admin_group Membership managed by users: example_member

Number of members added 1

NOTE

After you add a member manager to a host group, the update may take some time to spread to all clients in your Identity Management environment.

Verification

• Using the **ipa group-show** command to verify the host user and host group were added as member managers.

\$ ipa hostgroup-show group_name

Host-group: group_name

Member hosts: server.idm.example.com Member host-groups: project_admins

Membership managed by groups: admin_group Membership managed by users: example_member

Additional resources

- See ipa hostgroup-add-member-manager --help for more details.
- See **ipa hostgroup-show --help** for more details.

43.8. REMOVING IDM HOST GROUP MEMBER MANAGERS USING THE CLI

You can remove hosts as well as host groups as member managers from an IdM host group using a single command. Member managers can remove hosts group member managers from IdM host groups but cannot change the attributes of a host group.

Prerequisites

- Administrator privileges for managing IdM or User Administrator role.
- An active Kerberos ticket. For details, see Using kinit to log in to IdM manually .
- You must have the name of the existing member manager host group you are removing and the name of the host group they are managing.

Dracadura

Procedure

- 1. Optional: Use the **ipa hostgroup-find** command to find hosts and host groups.
- 2. To remove a member manager from a host group, use the **ipa hostgroup-remove-member-manager** command.

For example, to remove the user named *example_member* as a member manager from the group named *group_name*:

\$ ipa hostgroup-remove-member-manager group_name --user example_member

Host-group: group name

Member hosts: server.idm.example.com Member host-groups: project_admins Member of netgroups: group_name

Membership managed by groups: nested_group

Number of members removed 1

3. Use the **--groups** option to remove one or more host groups as a member manager from an IdM host group.

For example, to remove the host group named *nested_group* as a member manager from the group named *group_name*:

\$ ipa hostgroup-remove-member-manager group_name --groups nested_group

Host-group: group_name

Member hosts: server.idm.example.com Member host-groups: project_admins Member of netgroups: group_name

Number of members removed 1

NOTE

After you remove a member manager from a host group, the update may take some time to spread to all clients in your Identity Management environment.

Verification

• Use the **ipa group-show** command to verify that the host user and host group were removed as member managers.

\$ ipa hostgroup-show group name

Host-group: group_name

Member hosts: server.idm.example.com Member host-groups: project_admins

Additional resources

- See **ipa hostgroup-remove-member-manager --help** for more details.
- See **ipa hostgroup-show --help** for more details.

CHAPTER 44. MANAGING HOST GROUPS USING THE IDM WEB UI

Learn more about how to manage host groups and their members in the Web interface (Web UI) by using the following operations:

- Viewing host groups and their members
- Creating host groups
- Deleting host groups
- Adding host group members
- Removing host group members
- Adding host group member managers
- Removing host group member managers

For general information about host groups, see leveloffset=+1.

44.1. VIEWING HOST GROUPS IN THE IDM WEB UI

Follow this procedure to view IdM host groups using the Web interface (Web UI).

Prerequisites

- Administrator privileges for managing IdM or User Administrator role.
- You are logged-in to the IdM Web UI. For details, see Accessing the IdM Web UI in a web browser.

Procedure

- 1. Click **Identity>Groups**, and select the **Host Groups** tab. The **Host Groups** page lists the existing host groups and their descriptions. You can also search for a specific host group.
- 2. Click on a group in the list to display the hosts that belong to this group. You can limit results to direct or indirect members.
- 3. Select the **Host Groups** tab to display the host groups that belong to this group (nested host groups). You can limit results to direct or indirect members.

44.2. CREATING HOST GROUPS IN THE IDM WEB UI

Follow this procedure to create IdM host groups using the Web interface (Web UI).

Prerequisites

- Administrator privileges for managing IdM or User Administrator role.
- You are logged-in to the IdM Web UI. For details, see Accessing the IdM Web UI in a web browser.

Procedure

- 1. Click **Identity** → **Groups**, and select the **Host Groups** tab.
- 2. Click Add. The Add host group dialog appears.
- 3. Provide the information about the group: name (required) and description (optional).
- 4. Click Add to confirm.

44.3. DELETING HOST GROUPS IN THE IDM WEB UI

Follow this procedure to delete IdM host groups using the Web interface (Web UI).

Prerequisites

- Administrator privileges for managing IdM or User Administrator role.
- You are logged-in to the IdM Web UI. For details, see Accessing the IdM Web UI in a web browser.

Procedure

- 1. Click Identity>Groups and select the Host Groups tab.
- 2. Select the IdM host group to remove, and click **Delete**. A confirmation dialog appears.
- 3. Click Delete to confirm

NOTE

Removing a host group does not delete the group members from IdM.

44.4. ADDING HOST GROUP MEMBERS IN THE IDM WEB UI

Follow this procedure to add host group members in IdM using the web interface (Web UI).

Prerequisites

- Administrator privileges for managing IdM or User Administrator role.
- You are logged-in to the IdM Web UI. For details, see Accessing the IdM Web UI in a web browser.

- 1. Click **Identity** → **Groups** and select the **Host Groups** tab.
- 2. Click the name of the group to which you want to add members.
- 3. Click the tab **Hosts** or **Host groups** depending on the type of members you want to add. The corresponding dialog appears.
- 4. Select the hosts or host groups to add, and click the > arrow button to move them to the **Prospective** column.

5. Click Add to confirm.

44.5. REMOVING HOST GROUP MEMBERS IN THE IDM WEB UI

Follow this procedure to remove host group members in IdM using the web interface (Web UI).

Prerequisites

- Administrator privileges for managing IdM or User Administrator role.
- You are logged-in to the IdM Web UI. For details, see Accessing the IdM Web UI in a web browser.

Procedure

- 1. Click **Identity** → **Groups** and select the **Host Groups** tab.
- 2. Click the name of the group from which you want to remove members.
- 3. Click the tab **Hosts** or **Host groups** depending on the type of members you want to remove.
- 4. Select the checkbox next to the member you want to remove.
- 5. Click **Delete**. A confirmation dialog appears.
- 6. Click **Delete** to confirm. The selected members are deleted.

44.6. ADDING IDM HOST GROUP MEMBER MANAGERS USING THE WEB UI

Follow this procedure to add users or user groups as host group member managers in IdM using the web interface (Web UI). Member managers can add hosts group member managers to IdM host groups but cannot change the attributes of a host group.

Prerequisites

- Administrator privileges for managing IdM or User Administrator role.
- You are logged-in to the IdM Web UI. For details, see Accessing the IdM Web UI in a web browser.
- You must have the name of the host group you are adding as member managers and the name of the host group you want them to manage.

- 1. Click **Identity>Groups** and select the **Host Groups** tab.
- 2. Click the name of the group to which you want to add member managers.
- 3. Click the member managers tab **User Groups** or **Users** depending on the type of member managers you want to add. The corresponding dialog appears.
- 4. Click Add.

- 5. Select the users or user groups to add, and click the > arrow button to move them to the **Prospective** column.
- 6. Click Add to confirm.

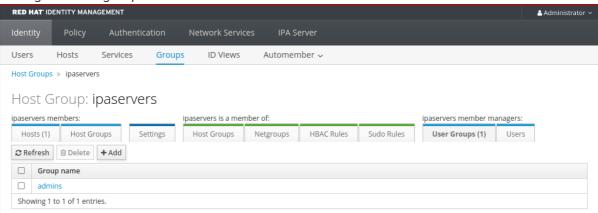

NOTE

After you add a member manager to a host group, the update may take some time to spread to all clients in your Identity Management environment.

Verification

 On the Host Group dialog, verify the user group or user has been added to the member managers list of groups or users.

44.7. REMOVING IDM HOST GROUP MEMBER MANAGERS USING THE WEB UI

Follow this procedure to remove users or user groups as host group member managers in IdM using the web interface (Web UI). Member managers can remove hosts group member managers from IdM host groups but cannot change the attributes of a host group.

Prerequisites

- Administrator privileges for managing IdM or User Administrator role.
- You are logged-in to the IdM Web UI. For details, see Accessing the IdM Web UI in a web browser.
- You must have the name of the existing member manager host group you are removing and the name of the host group they are managing.

- 1. Click Identity>Groups and select the Host Groups tab.
- 2. Click the name of the group from which you want to remove member managers.
- 3. Click the member managers tab **User Groups** or **Users** depending on the type of member managers you want to remove. The corresponding dialog appears.
- 4. Select the user or user groups to remove and click **Delete**.

5. Click **Delete** to confirm.

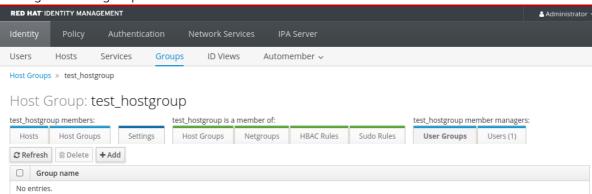

NOTE

After you remove a member manager from a host group, the update may take some time to spread to all clients in your Identity Management environment.

Verification

 On the Host Group dialog, verify the user group or user has been removed from the member managers list of groups or users.

CHAPTER 45. MANAGING HOST GROUPS BY USING ANSIBLE PLAYBOOKS

Learn how to manage host groups in Identity Management (IdM) by using Ansible playbooks in the Managing host groups using Ansible playbooks chapter of the *Using Ansible to install and manage Identity Management in RHEL* documentation.

CHAPTER 46. CONFIGURING HOST-BASED ACCESS CONTROL RULES

You can use host-based access control (HBAC) rules to manage access control in your Identity Management (IdM) domain. HBAC rules define which users or user groups can access specified hosts or host groups by using which services or services in a service group. For example, you can use HBAC rules to achieve the following goals:

- Limit access to a specified system in your domain to members of a specific user group.
- Allow only a specific service to be used to access the systems in your domain.

By default, IdM is configured with a default HBAC rule named **allow_all**, which allows universal access to every host for every user via every relevant service in the entire IdM domain.

You can fine-tune access to different hosts by replacing the default **allow_all** rule with your own set of HBAC rules. For centralized and simplified access control management, you can apply HBAC rules to user groups, host groups, or service groups instead of individual users, hosts, or services.

46.1. CONFIGURING HBAC RULES IN AN IDM DOMAIN USING THE WEBUI

To configure your domain for host-based access control, complete the following steps:

- 1. Create HBAC rules in the IdM WebUI.
- 2. Test the new HBAC rules.
- 3. Disable the default allow_all HBAC rule].

NOTE

Do not disable the **allow_all** rule before creating your custom HBAC rules as if you do so, no users will be able to access any hosts.

46.1.1. Creating HBAC rules in the IdM WebUI

To configure your domain for host-based access control using the IdM WebUI, follow the steps below. For the purposes of this example, the procedure shows you how to grant a single user, sysadmin access to all systems in the domain using any service.

NOTE

IdM stores the primary group of a user as a numerical value of the **gidNumber** attribute instead of a link to an IdM group object. For this reason, an HBAC rule can only reference a user's supplementary groups and not its primary group.

Prerequisites

• User sysadmin exists in IdM.

- 1. Select Policy>Host-Based Access Control>HBAC Rules
- 2. Click **Add** to start adding a new rule.
- 3. Enter a name for the rule, and click **Add and Edit** to open the HBAC rule configuration page.
- 4. In the **Who** area, select **Specified Users and Groups** Then click **Add** to add the users or groups.
- 5. Select the *sysadmin* user from the list of the **Available** users and click **>** to move to the list of **Prospective** users and click **Add**.
- 6. In the Accessing area, select Any Host to apply the HBAC rule to all hosts.
- 7. In the Via Service area, select Any Service to apply the HBAC rule to all services.

NOTE

Only the most common services and service groups are configured for HBAC rules by default.

- To display the list of services that are currently available, select Policy>Host-Based Access Control>HBAC Services.
- To display the list of service groups that are currently available, select Policy>Host-Based Access Control>HBAC Service Groups

To add more services and service groups, see Adding HBAC Service Entries for Custom HBAC Services and Adding HBAC Service Groups.

8. To save any changes you make on the **HBAC rule** configuration page, click **Save** at the top of the page.

46.1.2. Testing HBAC rules in the IdM WebUI

IdM allows you to test your HBAC configuration in various situations using simulated scenarios. Performing these simulated tests, you can discover misconfiguration problems or security risks before deploying HBAC rules in production.

IMPORTANT

Always test custom HBAC rules before you start using them in production.

Note that IdM does not test the effect of HBAC rules on trusted Active Directory (AD) users. Because the IdM LDAP directory does not store the AD data, IdM cannot resolve group membership of AD users when simulating HBAC scenarios.

- 1. Select Policy>Host-Based Access Control>HBAC Test
- 2. On the **Who** window, specify the user under whose identity you want to perform the test, and click **Next**.
- 3. On the Accessing window, specify the host that the user will attempt to access, and click Next.

- 4. On the Via Service window, specify the service that the user will attempt to use, and click Next.
- 5. On the **Rules** window, select the HBAC rules you want to test, and click **Next**. If you do not select any rule, all rules are tested.

Select Include Enabled to run the test on all rules whose status is Enabled. Select Include

Disabled to run the test on all rules whose status is Disabled. To view and change the status of

HBAC rules, select Policy>Host-Based Access Control>HBAC Rules

IMPORTANT

If the test runs on multiple rules, it passes successfully if at least one of the selected rules allows access.

- 6. On the Run Test window, click Run Test.
- 7. Review the test results:
 - If you see **ACCESS DENIED**, the user is not granted access in the test.
 - If you see ACCESS GRANTED, the user is able to access the host successfully.

By default, IdM lists all the tested HBAC rules when displaying the test results.

- Select **Matched** to display the rules that allowed successful access.
- Select **Unmatched** to display the rules that prevented access.

46.1.3. Disabling HBAC rules in the IdM WebUI

You can disable an HBAC rule but it only deactivates the rule and does not delete it. If you disable an HBAC rule, you can re-enable it later.

NOTE

Disabling HBAC rules is useful when you are configuring custom HBAC rules for the first time. To ensure that your new configuration is not overridden by the default **allow_all** HBAC rule, you must disable **allow_all**.

Procedure

- 1. Select Policy>Host-Based Access Control>HBAC Rules
- 2. Select the HBAC rule you want to disable.
- 3. Click **Disable**.
- 4. Click **OK** to confirm you want to disable the selected HBAC rule.

46.2. CONFIGURING HBAC RULES IN AN IDM DOMAIN USING THE CLI

To configure your domain for host-based access control, complete the following steps:

- 1. Create HBAC rules in the IdM CLI.
- 2. Test the new HBAC rules.

3. Disable the default allow_all HBAC rule.

NOTE

Do not disable the **allow_all** rule before creating your custom HBAC rules. If you disable it before creating your custom rules, access to all hosts for all users will be denied.

46.2.1. Creating HBAC rules in the IdM CLI

To configure your domain for host-based access control using the IdM CLI, follow the steps below. For the purposes of this example, the procedure shows you how to grant a single user, *sysadmin*, access to all systems in the domain using any service.

NOTE

IdM stores the primary group of a user as a numerical value of the **gidNumber** attribute instead of a link to an IdM group object. For this reason, an HBAC rule can only reference a user's supplementary groups and not its primary group.

Prerequisites

• User sysadmin exists in IdM.

Procedure

1. Use the **ipa hbacrule-add** command to add the rule.

\$ ipa hbacrule-add

Rule name: rule_name

Added HBAC rule "rule name"

Rule name: rule_name

Enabled: TRUE

2. To apply the HBAC rule to the sysadmin user only, use the **ipa hbacrule-add-user** command.

\$ ipa hbacrule-add-user --users=sysadmin

Rule name: rule_name
Rule name: rule name

Enabled: True Users: *sysadmin*

Number of members added 1

NOTE

To apply a HBAC rule to all users, use the **ipa hbacrule-mod** command and specify the all user category **--usercat=all**. Note that if the HBAC rule is associated with individual users or groups, **ipa hbacrule-mod --usercat=all** fails. In this situation, remove the users and groups using the **ipa hbacrule-remove-user** command.

3. Specify the target hosts. To apply the HBAC rule to all hosts, use the ipa hbacrule-mod command and specify the all host category:

\$ ipa hbacrule-mod rule_name --hostcat=all

Modified HBAC rule "rule name"

Rule name: rule name Host category: all **Enabled: TRUE** Users: sysadmin

NOTE

If the HBAC rule is associated with individual hosts or groups, ipa hbacrule-mod --hostcat=all fails. In this situation, remove the hosts and groups using the ipa hbacrule-remove-host command.

4. Specify the target HBAC services. To apply the HBAC rule to all services, use the **ipa hbacrulemod** command and specify the all service category:

\$ ipa hbacrule-mod rule_name --servicecat=all

Modified HBAC rule "rule name"

Rule name: rule_name Host category: all Service category: all Enabled: True

Users: sysadmin

NOTE

If the HBAC rule is associated with individual services or groups, ipa hbacrule-mod -**servicecat=all** fails. In this situation, remove the services and groups using the **ipa** hbacrule-remove-service command.

Verification

- Verify that the HBAC rule has been added correctly.
 - a. Use the **ipa hbacrule-find** command to verify that the HBAC rule exists in IdM.
 - b. Use the **ipa hbacrule-show** command to verify the properties of the HBAC rule.

Additional resources

- See **ipa hbacrule-add --help** for more details.
- See Adding HBAC service entries for custom HBAC services .
- See Adding HBAC service groups.

46.2.2. Testing HBAC rules in the IdM CLI

IdM allows you to test your HBAC configuration in various situations using simulated scenarios. Performing these simulated tests, you can discover misconfiguration problems or security risks before deploying HBAC rules in production.

IMPORTANT

Always test custom HBAC rules before you start using them in production.

Note that IdM does not test the effect of HBAC rules on trusted Active Directory (AD) users. Because the IdM LDAP directory does not store the AD data, IdM cannot resolve group membership of AD users when simulating HBAC scenarios.

Procedure

- Use the **ipa hbactest** command to test your HBAC rule. You have the option to test a single HBAC rule or multiple HBAC rules.
 - To test a single HBAC rule:

```
$ ipa hbactest --user=sysadmin --host=server.idm.example.com --service=sudo --
rules=rule_name
-------
Access granted: True
------
Matched rules: rule_name
```

- To test multiple HBAC rules:
 - a. Add a second rule only allowing the sysadmin to use **ssh** on all hosts:

```
$ ipa hbacrule-add --hostcat=all rule2_name
$ ipa hbacrule-add-user --users sysadmin rule2_name
$ ipa hbacrule-add-service --hbacsvcs=sshd rule2_name
Rule name: rule2_name
Host category: all
Enabled: True
Users: admin
HBAC Services: sshd
-------
Number of members added 1
```

b. Test multiple HBAC rules by running the following command:

In the output, **Matched rules** list the rules that allowed successful access while **Not matched** rules list the rules that prevented access. Note that if you do not specify the **rules** option, all rules are applied. Using **--rules** is useful to independently test each rule.

Additional resources

• See **ipa hbactest --help** for more information.

46.2.3. Disabling HBAC rules in the IdM CLI

You can disable an HBAC rule but it only deactivates the rule and does not delete it. If you disable an HBAC rule, you can re-enable it later.

NOTE

Disabling HBAC rules is useful when you are configuring custom HBAC rules for the first time. To ensure that your new configuration is not overridden by the default **allow_all** HBAC rule, you must disable **allow_all**.

Procedure

• Use the **ipa hbacrule-disable** command. For example, to disable the **allow_all** rule:

```
$ ipa hbacrule-disable allow_all
-----
Disabled HBAC rule "allow_all"
------
```

Additional resources

• See **ipa hbacrule-disable --help** for more details.

46.3. ADDING HBAC SERVICE ENTRIES FOR CUSTOM HBAC SERVICES

The most common services and service groups are configured for HBAC rules by default, but you can also configure any other pluggable authentication module (PAM) service as an HBAC service. This allows you to define custom PAM services in an HBAC rule. These PAM services files are in the **etc/pam.d** directory on RHEL systems.

NOTE

Adding a service as an HBAC service is not the same as adding a service to the domain. Adding a service to the domain makes it available to other resources in the domain, but it does not allow you to use the service in HBAC rules.

46.3.1. Adding HBAC service entries for custom HBAC services in the IdM WebUI

To add a custom HBAC service entry, follow the steps described below.

Procedure

1. Select Policy>Host-Based Access Control>HBAC Services.

- 2. Click **Add** to add an HBAC service entry.
- 3. Enter a name for the service, and click Add.

46.3.2. Adding HBAC service entries for custom HBAC services in the IdM CLI

To add a custom HBAC service entry, follow the steps described below.

Procedure

• Use the **ipa hbacsvc-add** command. For example, to add an entry for the **tftp** service:

```
$ ipa hbacsvc-add tftp
------
Added HBAC service "tftp"
------
Service name: tftp
```

Additional resources

See ipa hbacsvc-add --help for more details.

46.4. ADDING HBAC SERVICE GROUPS

HBAC service groups can simplify HBAC rules management. For example, instead of adding individual services to an HBAC rule, you can add a whole service group.

46.4.1. Adding HBAC service groups in the IdM WebUI

To add an HBAC service group in the IdM WebUI, follow the steps outlined below.

Procedure

- 1. Select Policy>Host-Based Access Control>HBAC Service Groups
- 2. Click **Add** to add an HBAC service group.
- 3. Enter a name for the service group, and click **Edit**.
- 4. On the service group configuration page, click **Add** to add an HBAC service as a member of the group.

46.4.2. Adding HBAC service groups in the IdM CLI

To add an HBAC service group in the IdM CLI, follow the steps outlined below.

Procedure

1. Use the **ipa hbacsvcgroup-add** command in your terminal to add an HBAC service group. For example, to add a group named *login*:

\$ ipa hbacsvcgroup-add Service group name: login Added HBAC service group "login"
----Service group name: login

2. Use the **ipa hbacsvcgroup-add-member** command to add an HBAC service as a member of the group. For example, to add the **sshd** service to the *login* group:

\$ ipa hbacsvcgroup-add-member

Service group name: login [member HBAC service]: sshd Service group name: login Member HBAC service: sshd

Number of members added 1

Additional resources

- See **ipa hbacsvcgroup-add --help** for more details.
- See **ipa hbacsvcgroup-add-member --help** for more details.

46.5. ADDITIONAL RESOURCES

• Ensuring the presence of host-based access control rules in IdM using Ansible playbooks .

CHAPTER 47. MANAGING PUBLIC SSH KEYS FOR USERS AND HOSTS

SSH (Secure Shell) is a protocol which provides secure communications between two systems using a client-server architecture. SSH allows users to log in to server host systems remotely and also allows one host machine to access another machine.

47.1. ABOUT THE SSH KEY FORMAT

IdM accepts the following two SSH key formats:

- OpenSSH-style key
- Raw RFC 4253-style key

Note that IdM automatically converts RFC 4253-style keys into OpenSSH-style keys before saving them into the IdM LDAP server.

The IdM server can identify the type of key, such as an RSA or DSA key, from the uploaded key blob. In a key file such as ~/.ssh/known_hosts, a key entry is identified by the hostname and IP address of the server, its type, and the key. For example:

host.example.com,1.2.3.4 ssh-rsa AAA...ZZZ==

This is different from a user public key entry, which has the elements in the order type key== comment:

"ssh-rsa ABCD1234...== ipaclient.example.com"

A key file, such as **id_rsa.pub**, consists of three parts: the key type, the key, and an additional comment or identifier. When uploading a key to IdM, you can upload all three key parts or only the key. If you only upload the key, IdM automatically identifies the key type, such as RSA or DSA, from the uploaded key.

If you use the host public key entry from the ~/.ssh/known_hosts file, you must reorder it to match the format of a user key, *type key== comment*:

ssh-rsa AAA...ZZZ== host.example.com,1.2.3.4

IdM can determine the key type automatically from the content of the public key. The comment is optional, to make identifying individual keys easier. The only required element is the public key blob.

IdM uses public keys stored in the following OpenSSH-style files:

- Host public keys are in the **known hosts** file.
- User public keys are in the **authorized_keys** file.

Additional resources

- See RFC 4716
- See RFC 4253

47.2. ABOUT IDM AND OPENSSH

During an IdM server or client installation, as part of the install script:

- An OpenSSH server and client is configured on the IdM client machine.
- SSSD is configured to store and retrieve user and host SSH keys in cache. This allows IdM to serve as a universal and centralized repository of SSH keys.

If you enable the SSH service during the client installation, an RSA key is created when the SSH service is started for the first time.

NOTE

When you run the **ipa-client-install** install script to add the machine as an IdM client, the client is created with two SSH keys, RSA and DSA.

As part of the installation, you can configure the following:

- Configure OpenSSH to automatically trust the IdM DNS records where the key fingerprints are stored using the **--ssh-trust-dns** option.
- Disable OpenSSH and prevent the install script from configuring the OpenSSH server using the **--no-sshd** option.
- Prevent the host from creating DNS SSHFP records with its own DNS entries using the --no-dns-sshfp option.

If you do not configure the server or client during installation, you can manually configure SSSD later. For information on how to manually configure SSSD, see Configuring SSSD to Provide a Cache for the OpenSSH Services. Note that caching SSH keys by SSSD requires administrative privileges on the local machines.

47.3. GENERATING SSH KEYS

You can generate an SSH key by using the OpenSSH ssh-keygen utility.

Procedure

1. To generate an RSA SSH key, run the following command:

\$ ssh-keygen -t rsa -C user@example.com Generating public/private rsa key pair.

Note if generating a host key, replace user@example.com with the required hostname, such as server.example.com,1.2.3.4.

- 2. Specify the file where you are saving the key or press enter to accept the displayed default location.
 - Enter file in which to save the key (/home/user/.ssh/id_rsa):

Note if generating a host key, save the key to a different location than the user's ~/.ssh/ directory so you do not overwrite any existing keys. for example, /home/user/.ssh/host keys.

3. Specify a passphrase for your private key or press enter to leave the passphrase blank.

Enter passphrase (empty for no passphrase):

Enter same passphrase again:

Your identification has been saved in /home/user/.ssh/id_rsa.

Your public key has been saved in /home/user/.ssh/id_rsa.pub.

The key fingerprint is:

SHA256:ONxjcMX7hJ5zly8F8ID9fpbqcuxQK+yIVLKDMsJPxGA user4@example.com

The key's randomart image is:

```
+---[RSA 3072]----+
| ..0 |
| .0 + |
| E.. 0 = |
| ..0 = 0 . + |
| +0S. = + 0.|
| ..0 .* B = . + |
| 0 + . X. + . = |
| + 0 0 .* + . . |
| . 0 = 0 . |
+----[SHA256]-----+
```

To upload this SSH key, use the public key string stored in the displayed file.

47.4. MANAGING PUBLIC SSH KEYS FOR USERS

Identity Management allows you to upload a public SSH key to a user entry. The user who has access to the corresponding private SSH key can use SSH to log into an IdM machine without using Kerberos credentials. Note that users can still authenticate by providing their Kerberos credentials if they are logging in from a machine where their private SSH key file is not available.

47.4.1. Uploading SSH keys for a user using the IdM Web UI

Identity Management allows you to upload a public SSH key to a user entry. The user who has access to the corresponding private SSH key can use SSH to log into an IdM machine without using Kerberos credentials.

Prerequisites

• Administrator privileges for managing the IdM Web UI or User Administrator role.

Procedure

- 1. Log into the IdM Web UI.
- 2. Go to the **Identity>Users** tab.
- 3. Click the name of the user to edit.
- 4. In the **Account Settings** section, click the SSH public keys **Add** button.
- 5. Paste the Base 64-encoded public key string into the **SSH public key** field.
- 6. Click Set.
- 7. Click **Save** at the top of the IdM Web UI window.

Verification

Under the Accounts Settings section, verify the key is listed under SSH public keys.

47.4.2. Uploading SSH keys for a user using the IdM CLI

Identity Management allows you to upload a public SSH key to a user entry. The user who has access to the corresponding private SSH key can use SSH to log into an IdM machine without using Kerberos credentials.

Prerequisites

• Administrator privileges for managing the IdM CLI or User Administrator role.

Procedure

1. Run the **ipa user-mod** command with the **--sshpubkey** option to upload the base64-encoded public key to the user entry.

\$ ipa user-mod user --sshpubkey="ssh-rsa AAAAB3Nza...SNc5dv== client.example.com"

Note in this example you upload the key type, the key, and the hostname identifier to the user entry.

- 2. To upload multiple keys, use **--sshpubkey** multiple times. For example, to upload two SSH keys:
 - --sshpubkey="AAAAB3Nza...SNc5dv==" --sshpubkey="RjlzYQo...ZEt0TAo="
- 3. To use command redirection and point to a file that contains the key instead of pasting the key string manually, use the following command:

\$ ipa user-mod user --sshpubkey="\$(cat ~/.ssh/id_rsa.pub)" --sshpubkey="\$(cat ~/.ssh/id_rsa2.pub)"

Verification

 Run the ipa user-show command to verify that the SSH public key is associated with the specified user:

\$ ipa user-show user

User login: user First name: user Last name: user

Home directory: /home/user

Login shell: /bin/sh

Principal name: user@IPA.TEST Principal alias: user@IPA.TEST Email address: user@ipa.test

UID: 1118800019 GID: 1118800019

SSH public key fingerprint:

SHA256:qGaqTZM60YPFTngFX0PtNPCKbluudwf1D2LqmDeOcuA

user@IPA.TEST (ssh-rsa)

Account disabled: False

Password: False

Member of groups: ipausers

Subordinate ids: 3167b7cc-8497-4ff2-ab4b-6fcb3cb1b047

Kerberos keys available: False

47.4.3. Deleting SSH keys for a user using the IdM Web UI

Follow this procedure to delete an SSH key from a user profile in the IdM Web UI.

Prerequisites

• Administrator privileges for managing the IdM Web UI or User Administrator role.

Procedure

- 1. Log into the IdM Web UI.
- 2. Go to the **Identity>Users** tab.
- 3. Click the name of the user to edit.
- 4. Under the **Account Settings** section, under **SSH public key**, click **Delete** next to the key you want to remove.
- 5. Click **Save** at the top of the page.

Verification

Under the Account Settings section, verify the key is no longer listed under SSH public keys.

47.4.4. Deleting SSH keys for a user using the IdM CLI

Follow this procedure to delete an SSH key from a user profile by using the IdM CLI.

Prerequisites

Administrator privileges for managing the IdM CLI or User Administrator role.

Procedure

To delete all SSH keys assigned to a user account, add the --sshpubkey option to the ipa user-mod command without specifying any key:

\$ ipa user-mod user --sshpubkey=

2. To only delete a specific SSH key or keys, use the **--sshpubkey** option to specify the keys you want to keep, omitting the key you are deleting.

Verification

 Run the ipa user-show command to verify that the SSH public key is no longer associated with the specified user:

\$ ipa user-show user

User login: user

First name: user Last name: user

Home directory: /home/user

Login shell: /bin/sh

Principal name: user@IPA.TEST Principal alias: user@IPA.TEST Email address: user@ipa.test

UID: 1118800019 GID: 1118800019 Account disabled: False Password: False

Member of groups: ipausers

Subordinate ids: 3167b7cc-8497-4ff2-ab4b-6fcb3cb1b047

Kerberos keys available: False

47.5. MANAGING PUBLIC SSH KEYS FOR HOSTS

OpenSSH uses public keys to authenticate hosts. One machine attempts to access another machine and presents its key pair. The first time the host authenticates, the administrator on the target machine has to approve the request manually. The machine then stores the host's public key in a **known_hosts** file. Any time that the remote machine attempts to access the target machine again, the target machine checks its **known_hosts** file and then grants access automatically to approved hosts.

47.5.1. Uploading SSH keys for a host using the IdM Web UI

Identity Management allows you to upload a public SSH key to a host entry. OpenSSH uses public keys to authenticate hosts.

Prerequisites

Administrator privileges for managing the IdM Web UI or User Administrator role.

Procedure

1. You can retrieve the key for your host from a ~/.ssh/known_hosts file. For example:

server.example.com,1.2.3.4 ssh-rsa
AAAAB3NzaC1yc2EAAAABIwAAAQEApvjBvSFSkTU0WQW4eOweeo0DZZ08F9Ud21xlLy6F
OhzwpXFGIyxvXZ52+siHBHbbqGL5+14N7UvEIruyslIHx9LYUR/pPKSMXCGyboLy5aTNI5OQ5
EHwrhVnFDIKXkvp45945R7SKYCUtRumm0Iw6wq0XD4o+ILeVbV3wmcB1bXs36ZvC/M6riefn
9PcJmh6vNCvIsbMY6S+FhkWUTTiOXJjUDYRLIwM273FfWhzHK+SSQXeBp/zIn1gFvJhSZMR
i9HZpDoqxLbBB9QIdIw6U4MIjNmKsSI/ASpkFm2GuQ7ZK9KuMItY2AoCuIRmRAdF8iYNHBT

XNfFurGogXwRDjQ==

You can also generate a host key. See Generating SSH keys.

2. Copy the public key from the key file. The full key entry has the form **host name,IP type key==**. Only the **key==** is required, but you can store the entire entry. To use all elements in the entry, rearrange the entry so it has the order **type key== [host name,IP]**.

cat /home/user/.ssh/host_keys.pub ssh-rsa AAAAB3NzaC1yc2E...tJG1PK2Mq++wQ== server.example.com,1.2.3.4

3. Log into the IdM Web UI.

- 4. Go to the **Identity>Hosts** tab.
- 5. Click the name of the host to edit.
- 6. In the Host Settings section, click the SSH public keys Add button.
- 7. Paste the public key for the host into the **SSH public key** field.
- 8. Click Set.
- 9. Click Save at the top of the IdM Web UI window.

Verification

• Under the Hosts Settings section, verify the key is listed under SSH public keys.

47.5.2. Uploading SSH keys for a host using the IdM CLI

Identity Management allows you to upload a public SSH key to a host entry. OpenSSH uses public keys to authenticate hosts. Host SSH keys are added to host entries in IdM, when the host is created using **host-add** or by modifying the entry later.

Note RSA and DSA host keys are created by the **ipa-client-install** command, unless the SSH service is explicitly disabled in the installation script.

Prerequisites

Administrator privileges for managing IdM or User Administrator role.

Procedure

1. Run the **host-mod** command with the **--sshpubkey** option to upload the base64-encoded public key to the host entry.

Because adding a host key changes the DNS Secure Shell fingerprint (SSHFP) record for the host, use the **--updatedns** option to update the host's DNS entry. For example:

\$ ipa host-mod --sshpubkey="ssh-rsa RjlzYQo==" --updatedns host1.example.com

A real key also usually ends with an equal sign (=) but is longer.

- 2. To upload more than one key, enter multiple --sshpubkey command-line parameters:
 - --sshpubkey="RjlzYQo==" --sshpubkey="ZEt0TAo=="

Note that a host can have multiple public keys.

3. After uploading the host keys, configure SSSD to use Identity Management as one of its identity domains and set up OpenSSH to use the SSSD tools for managing host keys, covered in Configuring SSSD to Provide a Cache for the OpenSSH Services.

Verification

 Run the ipa host-show command to verify that the SSH public key is associated with the specified host:

\$ ipa host-show client.ipa.test

..

SSH public key fingerprint:

SHA256:qGaqTZM60YPFTngFX0PtNPCKbluudwf1D2LqmDeOcuA client@IPA.TEST (ssh-rsa)

...

47.5.3. Deleting SSH keys for a host using the IdM Web UI

You can remove the host keys once they expire or are no longer valid. Follow the steps below to remove an individual host key by using the IdM Web UI.

Prerequisites

• Administrator privileges for managing the IdM Web UI or Host Administrator role.

Procedure

- 1. Log into the IdM Web UI.
- 2. Go to the **Identity>Hosts** tab.
- 3. Click the name of the host to edit.
- 4. Under the Host Settings section, click Delete next to the SSH public key you want to remove.
- 5. Click **Save** at the top of the page.

Verification

• Under the Host Settings section, verify the key is no longer listed under SSH public keys.

47.5.4. Deleting SSH keys for a host using the IdM CLI

You can remove the host keys once they expire or are no longer valid. Follow the steps below to remove an individual host key by using the IdM CLI.

Prerequisites

Administrator privileges for managing the IdM CLI or Host Administrator role.

Procedure

To delete all SSH keys assigned to a host account, add the --sshpubkey option to the ipa host-mod command without specifying any key:

\$ kinit admin

\$ ipa host-mod --sshpubkey= --updatedns host1.example.com

Note that it is good practice to use the **--updatedns** option to update the host's DNS entry.

IdM determines the key type automatically from the key, if the type is not included in the uploaded key.

Verification

• Run the **ipa host-show** command to verify that the SSH public key is no longer associated with the specified host:

\$ ipa host-show client.ipa.test

Host name: client.ipa.test

Platform: x86_64

Operating system: 4.18.0-240.el8.x86_64 Principal name: host/client.ipa.test@IPA.TEST Principal alias: host/client.ipa.test@IPA.TEST

Password: False

Member of host-groups: ipaservers

Roles: helpdesk

Member of netgroups: test Member of Sudo rule: test2 Member of HBAC rule: test

Keytab: True

Managed by: client.ipa.test, server.ipa.test

Users allowed to retrieve keytab: user1, user2, user3

CHAPTER 48. CONFIGURING THE DOMAIN RESOLUTION ORDER TO RESOLVE SHORT AD USER NAMES

By default, you must specify fully qualified names in the format **user_name@domain.com** or **domain.com\user_name** to resolve and authenticate users and groups from an Active Directory (AD) environment. Learn how to configure IdM servers and clients to resolve short AD usernames and group names.

48.1. HOW DOMAIN RESOLUTION ORDER WORKS

In Identity Management (IdM) environments with an Active Directory (AD) trust, Red Hat recommends that you resolve and authenticate users and groups by specifying their fully qualified names. For example:

- <idm_username>@idm.example.com for IdM users from the idm.example.com domain
- <ad_username>@ad.example.com for AD users from the ad.example.com domain

By default, if you perform user or group lookups using the *short name* format, such as **ad_username**, IdM only searches the IdM domain and fails to find the AD users or groups. To resolve AD users or groups using short names, change the order in which IdM searches multiple domains by setting the **domain resolution order** option.

You can set the domain resolution order centrally in the IdM database or in the SSSD configuration of individual clients. IdM evaluates domain resolution order in the following order of priority:

- The local /etc/sssd/sssd.conf configuration.
- The ID view configuration.
- The global IdM configuration.

Notes

- You must use fully qualified usernames if the SSSD configuration on the host includes the **default_domain_suffix** option and you want to make a request to a domain not specified with this option.
- If you use the **domain resolution order** option and query the **compat** tree, you might receive multiple user IDs (UIDs). If this might affect you, see Pagure bug report Inconsistent compat user objects for AD users when domain resolution order is set.

IMPORTANT

Do not use the **full_name_format** SSSD option on IdM clients or IdM servers. Using a non-default value for this option changes how usernames are displayed and might disrupt lookups in an IdM environment.

Additional resources

Active Directory Trust for Legacy Linux Clients

48.2. SETTING THE GLOBAL DOMAIN RESOLUTION ORDER ON AN IDM SERVER

This procedure sets the domain resolution order for all the clients in the IdM domain. This example sets the domain resolution order to search for users and groups in the following order:

- 1. Active Directory (AD) root domain ad.example.com
- 2. AD child domain **subdomain1.ad.example.com**
- 3. IdM domain idm.example.com

Prerequisites

• You have configured a trust with an AD environment.

Procedure

• Use the **ipa config-mod --domain-resolution-order** command to list the domains to be searched in your preferred order. Separate the domains with a colon (:).

```
[user@server ~]$ ipa config-mod --domain-resolution-
order='ad.example.com:subdomain1.ad.example.com:idm.example.com'
Maximum username length: 32
Home directory base: /home
...

Domain Resolution Order:
ad.example.com:subdomain1.ad.example.com:idm.example.com
```

Verification

• Verify you can retrieve user information for a user from the **ad.example.com** domain using only a short name.

```
[root@client ~]# id <ad_username> uid=1916901102(ad_username) gid=1916900513(domain users) groups=1916900513(domain users)
```

48.3. SETTING THE DOMAIN RESOLUTION ORDER FOR AN ID VIEW ON AN IDM SERVER

This procedure sets the domain resolution order for an ID view that you can apply to a specific set of IdM servers and clients. This example creates an ID view named **ADsubdomain1_first** for IdM host **client1.idm.example.com**, and sets the domain resolution order to search for users and groups in the following order:

- 1. Active Directory (AD) child domain **subdomain1.ad.example.com**
- 2. AD root domain ad.example.com
- 3. IdM domain idm.example.com

NOTE

The domain resolution order set in an ID view overrides the global domain resolution order, but it does not override any domain resolution order set locally in the SSSD configuration.

Prerequisites

• You have configured a trust with an AD environment.

Procedure

1. Create an ID view with the **--domain-resolution-order** option set.

[user@server ~]\$ ipa idview-add ADsubdomain1_first --desc "ID view for resolving AD subdomain1 first on client1.idm.example.com" --domain-resolution-order subdomain1.ad.example.com:ad.example.com:idm.example.com

Added ID View "ADsubdomain1_first"

ID View Name: ADsubdomain1_first

Description: ID view for resolving AD subdomain1 first on client1.idm.example.com

Domain Resolution Order: subdomain1.ad.example.com:ad.example.com:idm.example.com

2. Apply the ID view to IdM hosts.

```
[user@server ~]$ ipa idview-apply ADsubdomain1_first --hosts client1.idm.example.com
-------
Applied ID View "ADsubdomain1_first"
-------
hosts: client1.idm.example.com
-------
Number of hosts the ID View was applied to: 1
```

Verification

1. Display the details of the ID view.

```
[user@server ~]$ ipa idview-show ADsubdomain1_first --show-hosts
ID View Name: ADsubdomain1_first
Description: ID view for resolving AD subdomain1 first on client1.idm.example.com
Hosts the view applies to: client1.idm.example.com
Domain resolution order:
subdomain1.ad.example.com:ad.example.com:idm.example.com
```

2. Verify you can retrieve user information for a user from the **subdomain1.ad.example.com** domain using only a short name.

```
[root@client1 ~]# id <user_from_subdomain1> uid=1916901106(user_from_subdomain1) gid=1916900513(domain users) groups=1916900513(domain users)
```

48.4. USING ANSIBLE TO CREATE AN ID VIEW WITH A DOMAIN RESOLUTION ORDER

You can use the **ansible-freeipa idview** module to add, modify, and delete ID views in your Identity Management (IdM) deployment. For example, you can create an ID view with a domain resolution order to enable short name notation.

Short name notation substitutes a full user name from Active Directory (AD), such as aduser05@ad.example.com, with a short login, in this case aduser05. That means that when using SSH to log in to an IdM client, aduser05 can enter ssh aduser05@client.idm.example.com instead of ssh aduser05@ad.example.com@client.idm.example.com. The same applies to other commands, such as id.

Complete this procedure to use Ansible to:

- Define a string of colon-separated domains used for short name qualification. In the example, the string is ad.example.com:idm.example.com.
- Create an ID view that instructs SSSD to first search a user name in the first domain identified in the string. In the example, this is **ad.example.com**.
- Apply the ID view to a specific host. In the example, this is testhost.idm.example.com.

NOTE

You can apply only one ID view to an IdM client. Applying a new ID view automatically removes the previous ID view, if applicable.

Prerequisites

- On the control node:
 - You are using Ansible version 2.15 or later.
 - You have installed the **freeipa.ansible_freeipa** collection.
 - The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.
 - The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin_password** and that you have access to a file that stores the password protecting the **secret.yml** file.
- The target node, that is the node on which the freeipa.ansible_freeipa module is executed, is part of the IdM domain as an IdM client, server or replica.

Procedure

Navigate to your ~/MyPlaybooks/ directory and create an Ansible playbook file add-id-view-with-domain-resolution-order.yml with the following content:

- name: Playbook to add idview and apply it to an IdM client

hosts: ipaserver vars_files:

- /home/<user_name>/MyPlaybooks/secret.yml

become: false gather_facts: false

tasks:

- name: Add idview and apply it to testhost.idm.example.com

ipaadmin_password: "{{ ipaadmin_password }}"

name: test idview

host: testhost.idm.example.com

domain_resolution_order: "ad.example.com:ipa.example.com"

2. Run the playbook. Specify the playbook file, the file storing the password protecting the secret.yml file, and the inventory file:

\$ ansible-playbook --vault-password-file=password_file -v -i inventory add-id-view-with-domain-resolution-order.yml

Verification

- 1. SSH to testhost.idm.example.com.
- 2. Verify you can retrieve user information for a user from the **ad.example.com** domain using only a short name.

[root@testhost ~]# id aduser05 uid=1916901102(aduser05) gid=1916900513(domain users) groups=1916900513(domain users)

Additional resources

• The idview module in **ansible-freeipa** upstream docs

48.5. SETTING THE DOMAIN RESOLUTION ORDER IN SSSD ON AN IDM CLIENT

This procedure sets the domain resolution order in the SSSD configuration on an IdM client. This example configures IdM host **client2.idm.example.com** to search for users and groups in the following order:

- 1. Active Directory (AD) child domain **subdomain1.ad.example.com**
- 2. AD root domain ad.example.com
- 3. IdM domain idm.example.com

NOTE

The domain resolution order in the local SSSD configuration overrides any global and ID view domain resolution order.

Prerequisites

• You have configured a trust with an AD environment.

Procedure

- 1. Open the /etc/sssd/sssd.conf file in a text editor.
- 2. Set the **domain_resolution_order** option in the `` section of the file.

$$\label{local_com_adex} \begin{split} & domain_resolution_order = subdomain 1.ad. example.com, \ ad. example.com, \\ & idm. example.com \end{split}$$

- 3. Save and close the file.
- 4. Restart the SSSD service to load the new configuration settings.

[root@client2 ~]# systemctl restart sssd

Verification

• Verify you can retrieve user information for a user from the **subdomain1.ad.example.com** domain using only a short name.

[root@client2 \sim]# id <user_from_subdomain1> uid=1916901106(user_from_subdomain1) gid=1916900513(domain users) groups=1916900513(domain users)

48.6. ADDITIONAL RESOURCES

• Using an ID view to override a user attribute value on an IdM client

CHAPTER 49. ENABLING AUTHENTICATION USING AD USER PRINCIPAL NAMES IN IDM

49.1. USER PRINCIPAL NAMES IN AN AD FOREST TRUSTED BY IDM

As an Identity Management (IdM) administrator, you can allow AD users to use alternative **User Principal Names** (UPNs) to access resources in the IdM domain. A UPN is an alternative user login that AD users authenticate with in the format of **user_name@KERBEROS-REALM**. As an AD administrator, you can set alternative values for both **user_name** and **KERBEROS-REALM**, since you can configure both additional Kerberos aliases and UPN suffixes in an AD forest.

For example, if a company uses the Kerberos realm **AD.EXAMPLE.COM**, the default UPN for a user is **user@ad.example.com**. To allow your users to log in using their email addresses, for example **user@example.com**, you can configure **EXAMPLE.COM** as an alternative UPN in AD. Alternative UPNs (also known as *enterprise UPNs*) are especially convenient if your company has recently experienced a merge and you want to provide your users with a unified logon namespace.

UPN suffixes are only visible for IdM when defined in the AD forest root. As an AD administrator, you can define UPNs with the **Active Directory Domain and Trust** utility or the **PowerShell** command line tool.

NOTE

To configure UPN suffixes for users, Red Hat recommends to use tools that perform error validation, such as the **Active Directory Domain and Trust** utility.

Red Hat recommends against configuring UPNs through low-level modifications, such as using **Idapmodify** commands to set the **userPrincipalName** attribute for users, because Active Directory does not validate those operations.

After you define a new UPN on the AD side, run the **ipa trust-fetch-domains** command on an IdM server to retrieve the updated UPNs. See Ensuring that AD UPNs are up-to-date in IdM.

IdM stores the UPN suffixes for a domain in the multi-value attribute **ipaNTAdditionalSuffixes** of the subtree **cn=trusted_domain_name,cn=ad,cn=trusts,dc=idm,dc=example,dc=com**.

Additional resources

- How to script UPN suffix setup in AD forest root
- How to manually modify AD user entries and bypass any UPN suffix validation
- Trust controllers and trust agents

49.2. ENSURING THAT AD UPNS ARE UP-TO-DATE IN IDM

After you add or remove a User Principal Name (UPN) suffix in a trusted {AD} (AD) forest, refresh the information for the trusted forest on an IdM server.

Prerequisites

• IdM administrator credentials.

Procedure

• Enter the **ipa trust-fetch-domains** command. Note that a seemingly empty output is expected:

Verification

• Enter the **ipa trust-show** command to verify that the server has fetched the new UPN. Specify the name of the AD realm when prompted:

[root@ipaserver ~]# ipa trust-show Realm-Name: ad.example.com Realm-Name: ad.example.com Domain NetBIOS name: AD

Domain Security Identifier: S-1-5-21-796215754-1239681026-23416912

Trust direction: One-way trust
Trust type: Active Directory domain
UPN suffixes: example.com

The output shows that the **example.com** UPN suffix is now part of the **ad.example.com** realm entry.

49.3. GATHERING TROUBLESHOOTING DATA FOR AD UPN AUTHENTICATION ISSUES

Follow this procedure to gather troubleshooting data about the User Principal Name (UPN) configuration from your Active Directory (AD) environment and your IdM environment. If your AD users are unable to log in using alternate UPNs, you can use this information to narrow your troubleshooting efforts.

Prerequisites

- You must be logged in to an IdM Trust Controller or Trust Agent to retrieve information from an AD domain controller.
- You need **root** permissions to modify the following configuration files, and to restart IdM services.

Procedure

- 1. Open the /usr/share/ipa/smb.conf.empty configuration file in a text editor.
- 2. Add the following contents to the file.

[global] log level = 10

- 3. Save and close the /usr/share/ipa/smb.conf.empty file.
- 4. Open the /etc/ipa/server.conf configuration file in a text editor. If you do not have that file, create one.
- 5. Add the following contents to the file.

```
[global]
debug = True
```

- 6. Save and close the /etc/ipa/server.conf file.
- 7. Restart the Apache webserver service to apply the configuration changes:

```
[root@server ~]# systemctl restart httpd
```

- 8. Retrieve trust information from your AD domain:
 - [root@server ~]# ipa trust-fetch-domains <ad.example.com>
- 9. Review the debugging output and troubleshooting information in the following log files:
 - /var/log/httpd/error_log
 - /var/log/samba/log.*

Additional resources

• Using rpcclient to gather troubleshooting data for AD UPN authentication issues (Red Hat Knowledgebase)

CHAPTER 50. ENABLING AD USERS TO ADMINISTER IDM

50.1. ID OVERRIDES FOR AD USERS

You can centrally manage access of Active Directory (AD) users and groups to Identity Management (IdM) resources in a POSIX environment by adding an ID user override for an AD user as a member of an IdM group.

An ID override is a record describing what a specific Active Directory user or group properties should look like within a specific ID view, in this case the **Default Trust View**. With this feature, the IdM LDAP server is able to apply access control rules for the IdM group to the AD user.

AD users can use the self service features of IdM UI, for example to upload their SSH keys, or change their personal data. An AD administrator is able to fully administer IdM without having two different accounts and passwords.

NOTE

Currently, selected features in IdM may still be unavailable to AD users. For example, setting passwords for IdM users as an AD user from the IdM **admins** group might fail.

IMPORTANT

Do **not** use ID overrides of AD users for **sudo** rules in IdM. ID overrides of AD users represent only POSIX attributes of AD users, not AD users themselves.

50.2. USING ID OVERRIDES TO ENABLE AD USERS TO ADMINISTER IDM

Follow this procedure to create and use an ID override for an AD user to give that user rights identical to those of an IdM user. During this procedure, work on an IdM server that is configured as a trust controller or a trust agent.

Prerequisites

- A working IdM environment is set up. For details, see Installing Identity Management.
- A working trust between your IdM environment and AD is set up.

Procedure

1. As an IdM administrator, create an ID override for an AD user in the **Default Trust View**. For example, to create an ID override for the user **ad user@ad.example.com**:

kinit admin

ipa idoverrideuser-add 'default trust view' ad_user@ad.example.com

2. Add the ID override from the **Default Trust View** as a member of an IdM group. This must be a non-POSIX group, as it interacts with Active Directory.

If the group in question is a member of an IdM role, the AD user represented by the ID override gains all permissions granted by the role when using the IdM API, including both the command-line interface and the IdM web UI.

For example, to add the ID override for the **ad_user@ad.example.com** user to the IdM **admins** group:

ipa group-add-member admins --idoverrideusers=ad_user@ad.example.com

3. Alternatively, you can add the ID override to a role, such as the **User Administrator** role:

ipa role-add-member 'User Administrator' -- idoverrideusers=ad_user@ad.example.com

50.3. VERIFYING THAT AN AD USER CAN PERFORM CORRECT COMMANDS IN THE IDM CLI

This procedure checks that an {AD} (AD) user can log into Identity Management (IdM) command-line interface (CLI) and run commands appropriate for his role.

1. Destroy the current Kerberos ticket of the IdM administrator:

kdestroy -A

NOTE

The destruction of the Kerberos ticket is required because the GSSAPI implementation in MIT Kerberos chooses credentials from the realm of the target service by preference, which in this case is the IdM realm. This means that if a credentials cache collection, namely the **KCM**:, **KEYRING**:, or **DIR**: type of credentials cache is in use, a previously obtained **admin** or any other IdM principal's credentials will be used to access the IdM API instead of the AD user's credentials.

2. Obtain the Kerberos credentials of the AD user for whom an ID override has been created:

kinit ad_user@AD.EXAMPLE.COM Password for ad_user@AD.EXAMPLE.COM:

3. Test that the ID override of the AD user enjoys the same privileges stemming from membership in the IdM group as any IdM user in that group. If the ID override of the AD user has been added to the **admins** group, the AD user can, for example, create groups in IdM:

ipa group-add some-new-group
----Added group "some-new-group"
----Group name: some-new-group
GID: 1997000011

50.4. USING ANSIBLE TO ENABLE AN AD USER TO ADMINISTER IDM

You can use the **ansible-freeipa idoverrideuser** and **group** modules to create a user ID override for an {AD} (AD) user from a trusted AD domain and give that user rights identical to those of an IdM user. The procedure uses the example of the **Default Trust View** ID view to which the

administrator@addomain.com ID override is added in the first playbook task. In the next playbook task, the administrator@addomain.com ID override is added to the IdM admins group as a member. As a result, an AD administrator can administer IdM without having two different accounts and passwords.

Prerequisites

- You have configured your Ansible control node to meet the following requirements:
 - You are using Ansible version 2.15 or later.
 - You have installed the **freeipa.ansible_freeipa** collection.
 - The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.
 - The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin_password** and that you have access to a file that stores the password protecting the **secret.yml** file.
- The **ipaserver** host in the inventory file is configured as a trust controller or a trust agent.
- The target node, that is the node on which the **freeipa.ansible_freeipa** module is executed, is part of the IdM domain as an IdM client, server or replica.

Procedure

1. On your Ansible control node, create an **enable-ad-admin-to-administer-idm.yml** playbook with a task to add the **administrator@addomain.com** user override to the Default Trust View:

- name: Enable AD administrator to act as a FreeIPA admin

hosts: ipaserver become: false gather_facts: false

tasks:

name: Ensure idoverride for administrator@addomain.com in 'default trust view' ipaidoverrideuser:

ipaadmin_password: "{{ ipaadmin_password }}"

idview: "Default Trust View"

anchor: administrator@addomain.com

- 2. Use another playbook task in the same playbook to add the AD administrator user ID override to the **admins** group:
 - name: Add the AD administrator as a member of **admins** ipagroup:

ipaadmin_password: "{{ ipaadmin_password }}"

name: admins idoverrideuser:

- administrator@addomain.com
- 3. Save the file.
- 4. Run the Ansible playbook. Specify the playbook file, the file storing the password protecting the **secret.yml** file, and the inventory file:

\$ ansible-playbook --vault-password-file=password_file -v -i inventory enable-ad-admin-to-administer-idm.yml

Verification

1. Log in to the IdM client as the AD Administrator:

\$ ssh administrator@addomain.com@client.idm.example.com

2. Verify that you have obtained a valid ticket-granting ticket (TGT):

\$ klist

Ticket cache: KCM:325600500:99540

Default principal: Administrator@ADDOMAIN.COM

Valid starting Expires Service principal

02/04/2024 11:54:16 02/04/2024 21:54:16 krbtgt/ADDOMAIN.COM@ADDOMAIN.COM

renew until 02/05/2024 11:54:16

3. Verify your **admin** privileges in IdM:

\$ ipa user-add testuser --first=test --last=user

Added user "tuser"

User login: tuser First name: test Last name: user Full name: test user

[...]

Additional resources

• The idoverrideuser and ipagroup **ansible-freeipa** upstream documentation

CHAPTER 51. USING EXTERNAL IDENTITY PROVIDERS TO AUTHENTICATE TO IDM

You can associate users with external identity providers (IdP) that support the OAuth 2 device authorization flow.

When these users authenticate with the SSSD version available in RHEL 9.1 or later, they receive RHEL Identity Management (IdM) single sign-on capabilities with Kerberos tickets after performing authentication and authorization at the external IdP.

Notable features include:

- Adding, modifying, and deleting references to external IdPs with ipa idp-* commands.
- Enabling IdP authentication for users with the **ipa user-mod --user-auth-type=idp** command.

51.1. THE BENEFITS OF CONNECTING IDM TO AN EXTERNAL IDP

As an administrator, you might want to allow users stored in an external identity source, such as a cloud services provider, to access RHEL systems joined to your Identity Management (IdM) environment. To achieve this, you can delegate the authentication and authorization process of issuing Kerberos tickets for these users to that external entity.

You can use this feature to expand IdM's capabilities and allow users stored in external identity providers (IdPs) to access Linux systems managed by IdM.

51.2. HOW IDM INCORPORATES LOGINS VIA EXTERNAL IDPS

SSSD 2.7.0 contains the **sssd-idp** package, which implements the **idp** Kerberos pre-authentication method. This authentication method follows the OAuth 2.0 Device Authorization Grant flow to delegate authorization decisions to external IdPs:

- 1. An IdM client user initiates OAuth 2.0 Device Authorization Grant flow, for example, by attempting to retrieve a Kerberos TGT with the **kinit** utility at the command line.
- 2. A special code and website link are sent from the Authorization Server to the IdM KDC backend.
- 3. The IdM client displays the link and the code to the user. In this example, the IdM client outputs the link and code on the command line.
- 4. The user opens the website link in a browser, which can be on another host, a mobile phone, and so on:
 - a. The user enters the special code.
 - b. If necessary, the user logs in to the OAuth 2.0-based IdP.
 - c. The user is prompted to authorize the client to access information.
- 5. The user confirms access at the original device prompt. In this example, the user hits the **Enter** key at the command line.
- 6. The IdM KDC backend polls the OAuth 2.0 Authorization Server for access to user information.

What is supported:

- Logging in remotely via SSH with the **keyboard-interactive** authentication method enabled, which allows calling Pluggable Authentication Module (PAM) libraries.
- Logging in locally with the console via the **logind** service.
- Retrieving a Kerberos ticket-granting ticket (TGT) with the **kinit** utility.

What is currently not supported:

- Logging in to the IdM WebUI directly. To log in to the IdM WebUI, you must first acquire a Kerberos ticket.
- Logging in to Cockpit WebUI directly. To log in to the Cockpit WebUI, you must first acquire a Kerberos ticket.

Additional resources

- Authentication against external Identity Providers
- RFC 8628: OAuth 2.0 Device Authorization Grant

51.3. CREATING A REFERENCE TO AN EXTERNAL IDENTITY PROVIDER

To connect external identity providers (IdPs) to your Identity Management (IdM) environment, create IdP references in IdM. Complete this procedure to create a reference called **my-keycloak-idp** to an IdP based on the Keycloak template. For more reference templates, see Example references to different external IdPs in IdM.

Prerequisites

- You have registered IdM as an OAuth application to your external IdP, and obtained a client ID.
- You can authenticate as the IdM admin account.
- Your IdM servers are using RHEL 9.1 or later.
- Your IdM servers are using SSSD 2.7.0 or later.

Procedure

1. Authenticate as the IdM admin on an IdM server.

[root@server ~]# kinit admin

 Create a reference called my-keycloak-idp to an IdP based on the Keycloak template, where the --base-url option specifies the URL to the Keycloak server in the format servername.\$DOMAIN:\$PORT/prefix.

Identity Provider reference name: my-keycloak-idp

Authorization URI:

https://keycloak.idm.example.com:8443/auth/realms/main/protocol/openid-connect/auth Device authorization URI:

https://keycloak.idm.example.com: 8443/auth/realms/main/protocol/openid-connect/auth/device

Token URI: https://keycloak.idm.example.com:8443/auth/realms/main/protocol/openid-connect/token

User info URI: https://keycloak.idm.example.com:8443/auth/realms/main/protocol/openid-connect/userinfo

Client identifier: ipa_oidc_client

Scope: openid email

External IdP user identifier attribute: email

Verification

 Verify that the output of the ipa idp-show command shows the IdP reference you have created.

[root@server ~]# ipa idp-show my-keycloak-idp

Additional resources

- Example references to different external IdPs in IdM
- Options for the ipa idp-* commands to manage external identity providers in IdM
- The --provider option in the ipa idp-* commands
- ipa help idp-add

51.4. EXAMPLE REFERENCES TO DIFFERENT EXTERNAL IDPS IN IDM

The following table lists examples of the **ipa idp-add** command for creating references to different IdPs in IdM.

Identity Provider	Important options	Command example
Microsoft Identity Platform, Azure AD	provider microsoftorganization	# ipa idp-add <i>my-azure-idp</i> \provider microsoft \organization <i>main</i> \client-id < <i>azure_client_id</i> >
Google	provider google	# ipa idp-add <i>my-google-idp</i> \provider google \client-id < google_client_id>

Identity Provider	Important options	Command example
GitHub	provider github	# ipa idp-add my-github-idp \provider github \client-id < github_client_id>
Keycloak, Red Hat Single Sign-On	provider keycloakorganizationbase-url	# ipa idp-add my-keycloak-idp \provider keycloak \organization main \base-url keycloak.idm.example.com:8443/auth \client-id <keycloak_client_id> NOTE The Quarkus version of Keycloak 17 and later have removed the /auth/ portion of the URI. If you use the non-Quarkus distribution of Keycloak in your deployment, include /auth/ in thebase-url option.</keycloak_client_id>
Okta	provider okta	# ipa idp-add my-okta-idp \provider oktabase-url dev-12345.okta.com \client-id <okta_client_id></okta_client_id>

Additional resources

- Creating a reference to an external identity provider
- Options for the ipa idp-* commands to manage external identity providers in IdM
- The --provider option in the ipa idp-* commands
- Configure IdM to use Google as external IdP (Red Hat Knowledgebase)
- Configure IdM to use Entra ID (Azure AD) as external IdP (Red Hat Knowledgebase)
- Configure IdM to use GitHub as external IdP (Red Hat Knowledgebase)

51.5. OPTIONS FOR THE IPA IDP-* COMMANDS TO MANAGE EXTERNAL IDENTITY PROVIDERS IN IDM

The following examples show how to configure references to external IdPs based on the different IdP templates. Use the following options to specify your settings:

--provider

the predefined template for one of the known identity providers

--client-id

the OAuth 2.0 client identifier issued by the IdP during application registration. As the application registration procedure is specific to each IdP, refer to their documentation for details. If the external IdP is Red Hat Single Sign-On (SSO), see Creating an OpenID Connect Client.

--base-url

base URL for IdP templates, required by Keycloak and Okta

--organization

Domain or Organization ID from the IdP, required by Microsoft Azure

--secret

(optional) Use this option if you have configured your external IdP to require a secret from confidential OAuth 2.0 clients. If you use this option when creating an IdP reference, you are prompted for the secret interactively. Protect the client secret as a password.

NOTE

SSSD in RHEL 9.1 only supports non-confidential OAuth 2.0 clients that do not use a client secret. If you want to use external IdPs that require a client secret from confidential clients, you must use SSSD in RHEL 9.2 and later.

Additional resources

- Creating a reference to an external identity provider
- Example references to different external IdPs in IdM
- The --provider option in the ipa idp-* commands

51.6. MANAGING REFERENCES TO EXTERNAL IDPS

After you have created a reference to an external identity provider (IdP), you can find, show, modify, and delete that reference. This example shows you how to manage a reference to an external IdP named **keycloak-server1**.

Prerequisites

- You can authenticate as the IdM admin account.
- Your IdM servers are using RHEL 9.1 or later.
- Your IdM servers are using SSSD 2.7.0 or later.
- You have created a reference to an external IdP in IdM. See Creating a reference to an external identity provider.

Procedure

1. Authenticate as the IdM admin on an IdM server.

[root@server ~]# kinit admin

- 2. Manage the IdP reference.
 - To find an IdP reference whose entry includes the string **keycloak**:

[root@server ~]# ipa idp-find keycloak

- To display an IdP reference named my-keycloak-idp:
 - [root@server ~]# ipa idp-show my-keycloak-idp
- To modify an IdP reference, use the **ipa idp-mod** command. For example, to change the secret for an IdP reference named **my-keycloak-idp**, specify the **--secret** option to be prompted for the secret:
 - [root@server ~]# ipa idp-mod my-keycloak-idp --secret
- To delete an IdP reference named my-keycloak-idp:
 - [root@server ~]# ipa idp-del my-keycloak-idp

51.7. ENABLING AN IDM USER TO AUTHENTICATE VIA AN EXTERNAL IDP

To enable an IdM user to authenticate via an external identity provider (IdP), associate the external IdP reference you have previously created with the user account. This example associates the external IdP reference **keycloak-server1** with the user **idm-user-with-external-idp**.

Prerequisites

- Your IdM client and IdM servers are using RHEL 9.1 or later.
- Your IdM client and IdM servers are using SSSD 2.7.0 or later.
- You have created a reference to an external IdP in IdM. See Creating a reference to an external identity provider.

Procedure

Modify the IdM user entry to associate an IdP reference with the user account:

[root@server ~]# ipa user-mod idm-user-with-external-idp \
--idp my-keycloak-idp \
--idp-user-id idm-user-with-external-idp@idm.example.com \
--user-auth-type=idp

Modified user "idm-user-with-external-idp"
-----User login: idm-user-with-external-idp
First name: Test

Last name: User1

Home directory: /home/idm-user-with-external-idp

Login shell: /bin/sh

Principal name: idm-user-with-external-idp@idm.example.com Principal alias: idm-user-with-external-idp@idm.example.com Email address: idm-user-with-external-idp@idm.example.com

UID: 35000003 GID: 35000003

User authentication types: idp External IdP configuration: keycloak

External IdP user identifier: idm-user-with-external-idp@idm.example.com

Account disabled: False

Password: False

Member of groups: ipausers Kerberos keys available: False

Verification

 Verify that the output of the ipa user-show command for that user displays references to the IdP:

[root@server ~]# ipa user-show idm-user-with-external-idp

User login: idm-user-with-external-idp

First name: Test Last name: User1

Home directory: /home/idm-user-with-external-idp

Login shell: /bin/sh

Principal name: idm-user-with-external-idp@idm.example.com Principal alias: idm-user-with-external-idp@idm.example.com Email address: idm-user-with-external-idp@idm.example.com

ID: 35000003 GID: 35000003

User authentication types: idp External IdP configuration: keycloak

External IdP user identifier: idm-user-with-external-idp@idm.example.com

Account disabled: False Password: False

Member of groups: ipausers Kerberos keys available: False

51.8. RETRIEVING AN IDM TICKET-GRANTING TICKET AS AN EXTERNAL IDP USER

If you have delegated authentication for an Identity Management (IdM) user to an external identity provider (IdP), the IdM user can request a Kerberos ticket-granting ticket (TGT) by authenticating to the external IdP.

Complete this procedure to:

- 1. Retrieve and store an anonymous Kerberos ticket locally.
- 2. Request the TGT for the **idm-user-with-external-idp** user by using **kinit** with the **-T** option to enable Flexible Authentication via Secure Tunneling (FAST) channel to provide a secure connection between the Kerberos client and Kerberos Distribution Center (KDC).

Prerequisites

- Your IdM client and IdM servers use SSSD 2.7.0 or later.
- You have created a reference to an external IdP in IdM. See Creating a reference to an external identity provider.
- You have associated an external IdP reference with the user account. See Enabling an IdM user to authenticate via an external IdP.
- The user that you are initially logged in as has write permissions on a directory in the local filesystem.

Procedure

1. Use Anonymous PKINIT to obtain a Kerberos ticket and store it in a file named ./fast.ccache.

\$ kinit -n -c ./fast.ccache

2. Optional: View the retrieved ticket:

\$ klist -c fast.ccache

Ticket cache: FILE:fast.ccache

Default principal: WELLKNOWN/ANONYMOUS@WELLKNOWN:ANONYMOUS

Valid starting Expires Service principal

03/03/2024 13:36:37 03/04/2024 13:14:28

krbtgt/IDM.EXAMPLE.COM@IDM.EXAMPLE.COM

3. Begin authenticating as the IdM user, using the **-T** option to enable the FAST communication channel.

[root@client ~]# kinit -T ./fast.ccache idm-user-with-external-idp
Authenticate at https://oauth2.idp.com:8443/auth/realms/master/device?user_code=YHMQ-XKTL and press ENTER.:

- 4. In a browser, authenticate as the user at the website provided in the command output.
- 5. At the command line, press the **Enter** key to finish the authentication process.

Verification

• Display your Kerberos ticket information and confirm that the line **config: pa_type** shows **152** for pre-authentication with an external IdP.

[root@client ~]# klist -C Ticket cache: KCM:0:58420

Default principal: idm-user-with-external-idp@IDM.EXAMPLE.COM

Valid starting Expires Service principal

05/09/22 07:48:23 05/10/22 07:03:07 krbtgt/IDM.EXAMPLE.COM@IDM.EXAMPLE.COM

config: fast_avail(krbtgt/IDM.EXAMPLE.COM@IDM.EXAMPLE.COM) = yes

08/17/2022 20:22:45 08/18/2022 20:22:43

krbtgt/IDM.EXAMPLE.COM@IDM.EXAMPLE.COM

config: pa_type(krbtgt/IDM.EXAMPLE.COM@IDM.EXAMPLE.COM) = 152

The **pa_type = 152** indicates external IdP authentication.

51.9. LOGGING IN TO AN IDM CLIENT VIA SSH AS AN EXTERNAL IDP USER

To log in to an IdM client via SSH as an external identity provider (IdP) user, begin the login process on the command linel. When prompted, perform the authentication process at the website associated with the IdP, and finish the process at the Identity Management (IdM) client.

Prerequisites

- Your IdM client and IdM servers are using SSSD 2.7.0 or later.
- You have created a reference to an external IdP in IdM. See Creating a reference to an external identity provider.
- You have associated an external IdP reference with the user account. See Enabling an IdM user to authenticate via an external IdP.

Procedure

1. Attempt to log in to the IdM client via SSH.

[user@client ~]\$ ssh idm-user-with-external-idp@client.idm.example.com (idm-user-with-external-idp@client.idm.example.com) Authenticate at https://oauth2.idp.com:8443/auth/realms/main/device?user_code=XYFL-ROYR and press ENTER.

- 2. In a browser, authenticate as the user at the website provided in the command output.
- 3. At the command line, press the **Enter** key to finish the authentication process.

Verification

• Display your Kerberos ticket information and confirm that the line **config: pa_type** shows **152** for pre-authentication with an external IdP.

[idm-user-with-external-idp@client ~]\$ klist -C

Ticket cache: KCM:0:58420

Default principal: idm-user-with-external-idp@IDM.EXAMPLE.COM

Valid starting Expires Service principal

05/09/22 07:48:23 05/10/22 07:03:07 krbtgt/IDM.EXAMPLE.COM@IDM.EXAMPLE.COM

config: fast_avail(krbtgt/IDM.EXAMPLE.COM@IDM.EXAMPLE.COM) = yes

08/17/2022 20:22:45 08/18/2022 20:22:43

krbtgt/IDM.EXAMPLE.COM@IDM.EXAMPLE.COM

config: pa_type(krbtgt/IDM.EXAMPLE.COM@IDM.EXAMPLE.COM) = 152

51.10. THE -- PROVIDER OPTION IN THE IPA IDP-* COMMANDS

The following identity providers (IdPs) support OAuth 2.0 device authorization grant flow:

• Microsoft Identity Platform, including Azure AD

- Google
- GitHub
- Keycloak, including Red Hat Single Sign-On (SSO)
- Okta

When using the **ipa idp-add** command to create a reference to one of these external IdPs, you can specify the IdP type with the **--provider** option, which expands into additional options as described below:

--provider=microsoft

Microsoft Azure IdPs allow parametrization based on the Azure tenant ID, which you can specify with the **--organization** option to the **ipa idp-add** command. If you need support for the live.com IdP, specify the option **--organization common**.

Choosing --provider=microsoft expands to use the following options. The value of the -- organization option replaces the string **\${ipaidporg}** in the table.

Option	Value
auth-uri=URI	https://login.microsoftonline.com/\${ipaidporg}/oauth2/v2.0/authorize
dev-auth-uri=URI	https://login.microsoftonline.com/\${ipaidporg}/oauth2/v2.0/devicecode
token-uri=URI	https://login.microsoftonline.com/\${ipaidporg}/oauth2/v2.0/t oken
userinfo-uri=URI	https://graph.microsoft.com/oidc/userinfo
keys-uri=URI	https://login.microsoftonline.com/common/discovery/v2.0/k eys
scope=STR	openid email
idp-user-id=STR	email

--provider=google

Choosing **--provider=google** expands to use the following options:

Option	Value
auth-uri=URI	https://accounts.google.com/o/oauth2/auth
dev-auth-uri=URI	https://oauth2.googleapis.com/device/code
token-uri=URI	https://oauth2.googleapis.com/token

Option	Value
userinfo-uri=URI	https://openidconnect.googleapis.com/v1/userinfo
keys-uri=URI	https://www.googleapis.com/oauth2/v3/certs
scope=STR	openid email
idp-user-id=STR	email

--provider=github

Choosing **--provider=github** expands to use the following options:

Option	Value
auth-uri=URI	https://github.com/login/oauth/authorize
dev-auth-uri=URI	https://github.com/login/device/code
token-uri=URI	https://github.com/login/oauth/access_token
userinfo-uri=URI	https://openidconnect.googleapis.com/v1/userinfo
keys-uri=URI	https://api.github.com/user
scope=STR	user
idp-user-id=STR	login

--provider=keycloak

With Keycloak, you can define multiple realms or organizations. Since it is often a part of a custom deployment, both base URL and realm ID are required, and you can specify them with the **--base-url** and **--organization** options to the **ipa idp-add** command:

[root@client ~]# ipa idp-add MySSO --provider keycloak \

- --org main --base-url keycloak.domain.com:8443/auth \
- --client-id <your-client-id>

Choosing --provider=keycloak expands to use the following options. The value you specify in the --base-url option replaces the string **\${ipaidpbaseurl}** in the table, and the value you specify for the --organization `option replaces the string `**\${ipaidporg}**}.

Option	Value
auth-uri=URI	https://\${ipaidpbaseurl}/realms/\${ipaidporg}/protocol/openid-connect/auth

Option	Value
dev-auth-uri=URI	https://\${ipaidpbaseurl}/realms/\${ipaidporg}/protocol/openi d-connect/auth/device
token-uri=URI	https://\${ipaidpbaseurl}/realms/\${ipaidporg}/protocol/openi d-connect/token
userinfo-uri=URI	https://\${ipaidpbaseurl}/realms/\${ipaidporg}/protocol/openi d-connect/userinfo
scope=STR	openid email
idp-user-id=STR	email

--provider=okta

After registering a new organization in Okta, a new base URL is associated with it. You can specify this base URL with the **--base-url** option to the **ipa idp-add** command:

[root@client ~]# ipa idp-add MyOkta --provider okta --base-url dev-12345.okta.com --client-id <your-client-id>

Choosing --provider=okta expands to use the following options. The value you specify for the -- base-url option replaces the string **\${ipaidpbaseurl}** in the table.

Option	Value
auth-uri=URI	https://\${ipaidpbaseurl}/oauth2/v1/authorize
dev-auth-uri=URI	https://\${ipaidpbaseurl}/oauth2/v1/device/authorize
token-uri=URI	https://\${ipaidpbaseurl}/oauth2/v1/token
userinfo-uri=URI	https://\${ipaidpbaseurl}/oauth2/v1/userinfo
scope=STR	openid email
idp-user-id=STR	email

• Using Ansible to delegate authentication for IdM users to external identity providers

CHAPTER 52. USING CONSTRAINED DELEGATION IN IDM

Learn more about how you can use the constrained delegation feature in Identity Management (IdM):

- Constrained delegation in Identity Management describes how constrained delegation works.
- Configuring a web console to allow a user authenticated with a smart card to SSH to a remote
 host without being asked to authenticate again describes a use case for constrained delegation
 in the context of using the Red Hat Enterprise Linux web console to SSH to a remote host
 without requiring authentication.
- Using Ansible to configure a web console to allow a user authenticated with a smart card to SSH
 to a remote host without being asked to authenticate again describes a use case for constrained
 delegation in the context of using Ansible to configure the use of the Red Hat Enterprise Linux
 web console to SSH to a remote host without requiring authentication.
- Configuring a web console client to allow a user authenticated with a smart card to run sudo without being asked to authenticate describes a use case for constrained delegation in the context of using the Red Hat Enterprise Linux web console to run **sudo** without requiring authentication.
- Using Ansible to configure a web console to allow a user authenticated with a smart card to run sudo without being asked to authenticate again describes a use case for constrained delegation in the context of using Ansible to configure the use of the Red Hat Enterprise Linux web console to run **sudo** without requiring authentication.

52.1. CONSTRAINED DELEGATION IN IDENTITY MANAGEMENT

The Service for User to Proxy (**S4U2proxy**) extension provides a service that obtains a service ticket to another service on behalf of a user. This feature is known as **constrained delegation**. The second service is typically a proxy performing some work on behalf of the first service, under the authorization context of the user. Using constrained delegation eliminates the need for the user to delegate their full ticket-granting ticket (TGT).

Identity Management (IdM) traditionally uses the Kerberos **S4U2proxy** feature to allow the web server framework to obtain an LDAP service ticket on the user's behalf. The IdM-AD trust system also uses constrained delegation to obtain a **cifs** principal.

You can use the **S4U2proxy** feature to configure a web console client to allow an IdM user that has authenticated with a smart card to achieve the following:

- Run commands with superuser privileges on the RHEL host on which the web console service is running without being asked to authenticate again.
- Access a remote host using **SSH** and access services on the host without being asked to authenticate again.

Additional resources

- S4U2proxy
- Service constrained delegation

52.2. CONFIGURING A WEB CONSOLE TO ALLOW A USER AUTHENTICATED WITH A SMART CARD TO SSH TO A REMOTE HOST WITHOUT BEING ASKED TO AUTHENTICATE AGAIN

After you have logged in to a user account on the RHEL web console, as an Identity Management (IdM) system administrator you might need to connect to remote machines by using the **SSH** protocol. You can use the constrained delegation feature to use **SSH** without being asked to authenticate again.

Follow this procedure to configure the web console to use constrained delegation. In the example below, the web console session runs on the **myhost.idm.example.com** host and it is being configured to access the **remote.idm.example.com** host by using **SSH** on behalf of the authenticated user.

Prerequisites

- You have obtained an IdM **admin** ticket-granting ticket (TGT).
- You have **root** access to **remote.idm.example.com**.
- The web console service is present in IdM.
- The remote.idm.example.com host is present in IdM.
- The web console has created an S4U2Proxy Kerberos ticket in the user session. To verify that
 this is the case, log in to the web console as an IdM user, open the Terminal page, and enter:

\$ klist

Ticket cache: FILE:/run/user/1894000001/cockpit-session-3692.ccache

Default principal: user@IDM.EXAMPLE.COM

Valid starting Expires Service principal

07/30/21 09:19:06 07/31/21 09:19:06

HTTP/myhost.idm.example.com@IDM.EXAMPLE.COM

07/30/21 09:19:06 07/31/21 09:19:06 krbtgt/IDM.EXAMPLE.COM@IDM.EXAMPLE.COM for client HTTP/myhost.idm.example.com@IDM.EXAMPLE.COM

Procedure

- 1. Create a list of the target hosts that can be accessed by the delegation rule:
 - a. Create a service delegation target:
 - \$ ipa servicedelegationtarget-add cockpit-target
 - b. Add the target host to the delegation target:
 - \$ ipa servicedelegationtarget-add-member cockpit-target \
 --principals=host/remote.idm.example.com@IDM.EXAMPLE.COM
- 2. Allow **cockpit** sessions to access the target host list by creating a service delegation rule and adding the **HTTP** service Kerberos principal to it:
 - a. Create a service delegation rule:
 - \$ ipa servicedelegationrule-add cockpit-delegation

b. Add the web console client to the delegation rule:

\$ ipa servicedelegationrule-add-member cockpit-delegation \
--principals=HTTP/myhost.idm.example.com@IDM.EXAMPLE.COM

c. Add the delegation target to the delegation rule:

\$ ipa servicedelegationrule-add-target cockpit-delegation \
--servicedelegationtargets=cockpit-target

- 3. Enable Kerberos authentication on the **remote.idm.example.com** host:
 - a. SSH to remote.idm.example.com as root.
 - b. Open the /etc/ssh/sshd_config file for editing.
 - c. Enable **GSSAPIAuthentication** by uncommenting the **GSSAPIAuthentication no** line and replacing it with **GSSAPIAuthentication yes**.
- 4. Restart the **SSH** service on **remote.idm.example.com** so that the above changes take effect immediately:

\$ systemctl try-restart sshd.service

Additional resources

- Logging in to the web console with smart cards
- Constrained delegation in Identity Management

52.3. USING ANSIBLE TO CONFIGURE A WEB CONSOLE TO ALLOW A USER AUTHENTICATED WITH A SMART CARD TO SSH TO A REMOTE HOST WITHOUT BEING ASKED TO AUTHENTICATE AGAIN

After you have logged in to a user account on the RHEL web console, as an Identity Management (IdM) system administrator you might need to connect to remote machines by using the **SSH** protocol. You can use the constrained delegation feature to use **SSH** without being asked to authenticate again.

Follow this procedure to use the **servicedelegationrule** and **servicedelegationtarget ansible-freeipa** modules to configure a web console to use constrained delegation. In the example below, the web console session runs on the **myhost.idm.example.com** host and it is being configured to access the **remote.idm.example.com** host by using **SSH** on behalf of the authenticated user.

Prerequisites

- The IdM **admin** password.
- root access to remote.idm.example.com.
- The web console service is present in IdM.
- The **remote.idm.example.com** host is present in IdM.

• The web console has created an **S4U2Proxy** Kerberos ticket in the user session. To verify that this is the case, log in to the web console as an IdM user, open the **Terminal** page, and enter:

\$ klist

Ticket cache: FILE:/run/user/1894000001/cockpit-session-3692.ccache

Default principal: user@IDM.EXAMPLE.COM

Valid starting Expires Service principal

07/30/21 09:19:06 07/31/21 09:19:06

HTTP/myhost.idm.example.com@IDM.EXAMPLE.COM

07/30/21 09:19:06 07/31/21 09:19:06 krbtgt/IDM.EXAMPLE.COM@IDM.EXAMPLE.COM for client HTTP/myhost.idm.example.com@IDM.EXAMPLE.COM

- You have configured your Ansible control node to meet the following requirements:
 - You are using Ansible version 2.15 or later.
 - You have installed the **freeipa.ansible freeipa** collection.
 - The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.
 - The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin_password** and that you have access to a file that stores the password protecting the **secret.yml** file.
- The target node, that is the node on which the **freeipa.ansible_freeipa** module is executed, is part of the IdM domain as an IdM client, server or replica.

Procedure

1. Navigate to your ~/MyPlaybooks/ directory:

\$ cd ~/MyPlaybooks/

- 2. Create a **web-console-smart-card-ssh.yml** playbook with the following content:
 - a. Create a task that ensures the presence of a delegation target:

- name: Playbook to create a constrained delegation target

 name: Playbook to create a constrained delegation targe hosts: ipaserver

vars_files:

- /home/user_name/MyPlaybooks/secret.yml tasks:
- name: Ensure servicedelegationtarget web-console-delegation-target is present freeipa.ansible_freeipa.ipaservicedelegationtarget: ipaadmin_password: "{{ ipaadmin_password }}" name: web-console-delegation-target
- b. Add a task that adds the target host to the delegation target:
 - name: Ensure servicedelegationtarget web-console-delegation-target member principal host/remote.idm.example.com@IDM.EXAMPLE.COM is present freeipa.ansible_freeipa.ipaservicedelegationtarget:

ipaadmin_password: "{{ ipaadmin_password }}"

name: web-console-delegation-target

principal: host/remote.idm.example.com@IDM.EXAMPLE.COM

action: member

c. Add a task that ensures the presence of a delegation rule:

 name: Ensure servicedelegationrule delegation-rule is present freeipa.ansible_freeipa.ipaservicedelegationrule: ipaadmin_password: "{{ ipaadmin_password }}" name: web-console-delegation-rule

d. Add a task that ensures that the Kerberos principal of the web console client service is a member of the constrained delegation rule:

- name: Ensure the Kerberos principal of the web console client service is added to the servicedelegationrule web-console-delegation-rule

 $free ip a. ansible_free ip a. ip a service de legation rule:$

ipaadmin_password: "{{ ipaadmin_password }}"

name: web-console-delegation-rule

principal: HTTP/myhost.idm.example.com

action: member

e. Add a task that ensures that the constrained delegation rule is associated with the webconsole-delegation-target delegation target:

- name: Ensure a constrained delegation rule is associated with a specific delegation target

freeipa.ansible_freeipa.ipaservicedelegationrule:

ipaadmin_password: "{{ ipaadmin_password }}"

name: web-console-delegation-rule target: web-console-delegation-target

action: member

- 3. Save the file.
- 4. Run the Ansible playbook. Specify the playbook file, the file storing the password protecting the **secret.yml** file, and the inventory file:

\$ ansible-playbook --vault-password-file=password_file -v -i inventory web-console-smart-card-ssh.yml

- 5. Enable Kerberos authentication on **remote.idm.example.com**:
 - a. SSH to remote.idm.example.com as root.
 - b. Open the /etc/ssh/sshd_config file for editing.
 - c. Enable **GSSAPIAuthentication** by uncommenting the **GSSAPIAuthentication no** line and replacing it with **GSSAPIAuthentication yes**.

52.4. CONFIGURING A WEB CONSOLE TO ALLOW A USER AUTHENTICATED WITH A SMART CARD TO RUN SUDO WITHOUT BEING ASKED TO AUTHENTICATE AGAIN

After you have logged in to a user account on the RHEL web console, as an Identity Management (IdM) system administrator you might need to run commands with superuser privileges. You can use the constrained delegation feature to run **sudo** on the system without being asked to authenticate again.

Follow this procedure to configure a web console to use constrained delegation. In the example below, the web console session runs on the **myhost.idm.example.com** host.

Prerequisites

- You have obtained an IdM admin ticket-granting ticket (TGT).
- The web console service is present in IdM.
- The **myhost.idm.example.com** host is present in IdM.
- You have enabled **admin sudo** access to domain administrators on the IdM server.
- The web console has created an **S4U2Proxy** Kerberos ticket in the user session. To verify that this is the case, log in to the web console as an IdM user, open the **Terminal** page, and enter:

\$ klist

Ticket cache: FILE:/run/user/1894000001/cockpit-session-3692.ccache

Default principal: user@IDM.EXAMPLE.COM

Valid starting Expires Service principal

07/30/21 09:19:06 07/31/21 09:19:06

HTTP/myhost.idm.example.com@IDM.EXAMPLE.COM

07/30/21 09:19:06 07/31/21 09:19:06 krbtgt/IDM.EXAMPLE.COM@IDM.EXAMPLE.COM for client HTTP/myhost.idm.example.com@IDM.EXAMPLE.COM

Procedure

- 1. Create a list of the target hosts that can be accessed by the delegation rule:
 - a. Create a service delegation target:
 - \$ ipa servicedelegationtarget-add cockpit-target
 - b. Add the target host to the delegation target:

- \$ ipa servicedelegationtarget-add-member cockpit-target \
 --principals=host/myhost.idm.example.com@IDM.EXAMPLE.COM
- 2. Allow **cockpit** sessions to access the target host list by creating a service delegation rule and adding the **HTTP** service Kerberos principal to it:
 - a. Create a service delegation rule:
 - \$ ipa servicedelegationrule-add cockpit-delegation
 - b. Add the web console service to the delegation rule:
 - \$ ipa servicedelegationrule-add-member cockpit-delegation \
 --principals=HTTP/myhost.idm.example.com@IDM.EXAMPLE.COM
 - c. Add the delegation target to the delegation rule:
 - \$ ipa servicedelegationrule-add-target cockpit-delegation \
 --servicedelegationtargets=cockpit-target
- 3. Enable **pam_sss_gss**, the PAM module for authenticating users over the Generic Security Service Application Program Interface (GSSAPI) in cooperation with the System Security Services Daemon (SSSD):
 - a. Open the /etc/sssd/sssd.conf file for editing.
 - b. Specify that **pam_sss_gss** can provide authentication for the **sudo** and **sudo -i** commands in IdM your domain:

[domain/idm.example.com]
pam_gssapi_services = sudo, sudo-i

- c. Save and exit the file.
- d. Open the /etc/pam.d/sudo file for editing.
- e. Insert the following line to the top of the **#%PAM-1.0** list to allow, but not require, GSSAPI authentication for **sudo** commands:

auth sufficient pam_sss_gss.so

- f. Save and exit the file.
- 4. Restart the **SSSD** service so that the above changes take effect immediately:
 - \$ systemctl restart sssd

Additional resources

- Logging in to the web console with smart cards

52.5. USING ANSIBLE TO CONFIGURE A WEB CONSOLE TO ALLOW A USER AUTHENTICATED WITH A SMART CARD TO RUN SUDO WITHOUT BEING ASKED TO AUTHENTICATE AGAIN

After you have logged in to a user account on the RHEL web console, as an Identity Management (IdM) system administrator you might need to run commands with superuser privileges. You can use the constrained delegation feature to run **sudo** on the system without being asked to authenticate again.

Follow this procedure to use the **ipaservicedelegationrule** and **ipaservicedelegationtarget ansible-freeipa** modules to configure a web console to use constrained delegation. In the example below, the web console session runs on the **myhost.idm.example.com** host.

Prerequisites

- You have obtained an IdM **admin** ticket-granting ticket (TGT) by authenticating to the web console session with a smart card..
- The web console service has been enrolled into IdM.
- The myhost.idm.example.com host is present in IdM.
- You have enabled **admin sudo** access to domain administrators on the IdM server .
- The web console has created an **S4U2Proxy** Kerberos ticket in the user session. To verify that this is the case, log in to the web console as an IdM user, open the **Terminal** page, and enter:

\$ klist

Ticket cache: FILE:/run/user/1894000001/cockpit-session-3692.ccache

Default principal: user@IDM.EXAMPLE.COM

Valid starting Expires Service principal

07/30/21 09:19:06 07/31/21 09:19:06

HTTP/myhost.idm.example.com@IDM.EXAMPLE.COM

07/30/21 09:19:06 07/31/21 09:19:06 krbtgt/IDM.EXAMPLE.COM@IDM.EXAMPLE.COM for client HTTP/myhost.idm.example.com@IDM.EXAMPLE.COM

- You have configured your Ansible control node to meet the following requirements:
 - You are using Ansible version 2.15 or later.
 - You have installed the **freeipa.ansible freeipa** collection.
 - The example assumes that in the ~/MyPlaybooks/ directory, you have created an Ansible inventory file with the fully-qualified domain name (FQDN) of the IdM server.
 - The example assumes that the **secret.yml** Ansible vault stores your **ipaadmin_password** and that you have access to a file that stores the password protecting the **secret.yml** file.
- The target node, that is the node on which the **freeipa.ansible_freeipa** module is executed, is part of the IdM domain as an IdM client, server or replica.

Procedure

1. On your Ansible control node, navigate to your ~/MyPlaybooks/ directory:

\$ cd ~/MyPlaybooks/

- 2. Create a web-console-smart-card-sudo.yml playbook with the following content:
 - a. Create a task that ensures the presence of a delegation target:

- name: Playbook to create a constrained delegation target

hosts: ipaserver

vars_files:

- /home/user_name/MyPlaybooks/secret.yml

- name: Ensure servicedelegationtarget named sudo-web-console-delegation-target is present

freeipa.ansible_freeipa.ipaservicedelegationtarget: ipaadmin_password: "{{ ipaadmin_password }}" name: sudo-web-console-delegation-target

- b. Add a task that adds the target host to the delegation target:
 - name: Ensure that a member principal named host/myhost.idm.example.com@IDM.EXAMPLE.COM is present in a service delegation target named sudo-web-console-delegation-target

freeipa.ansible_freeipa.ipaservicedelegationtarget:

ipaadmin_password: "{{ ipaadmin_password }}"

name: sudo-web-console-delegation-target

principal: host/myhost.idm.example.com@IDM.EXAMPLE.COM

action: member

- c. Add a task that ensures the presence of a delegation rule:
 - name: Ensure servicedelegationrule named sudo-web-console-delegation-rule is present

freeipa.ansible_freeipa.ipaservicedelegationrule:

ipaadmin_password: "{{ ipaadmin_password }}"

name: sudo-web-console-delegation-rule

- d. Add a task that ensures that the Kerberos principal of the web console service is a member of the constrained delegation rule:
 - name: Ensure the Kerberos principal of the web console service is added to the service delegation rule named sudo-web-console-delegation-rule

freeipa.ansible_freeipa.ipaservicedelegationrule:

ipaadmin_password: "{{ ipaadmin_password }}"

name: sudo-web-console-delegation-rule principal: HTTP/myhost.idm.example.com

action: member

- e. Add a task that ensures that the constrained delegation rule is associated with the sudoweb-console-delegation-target delegation target:
 - name: Ensure a constrained delegation rule is associated with a specific delegation target

freeipa.ansible_freeipa.ipaservicedelegationrule: ipaadmin_password: "{{ ipaadmin_password }}" name: sudo-web-console-delegation-rule target: sudo-web-console-delegation-target action: member

3. Save the file.

4. Run the Ansible playbook. Specify the playbook file, the file storing the password protecting the **secret.yml** file, and the inventory file:

\$ ansible-playbook --vault-password-file=password_file -v -i inventory web-console-smart-card-sudo.yml

- 5. Enable **pam_sss_gss**, the PAM module for authenticating users over the Generic Security Service Application Program Interface (GSSAPI) in cooperation with the System Security Services Daemon (SSSD):
 - a. Open the /etc/sssd/sssd.conf file for editing.
 - b. Specify that **pam_sss_gss** can provide authentication for the **sudo** and **sudo -i** commands in IdM your domain:

[domain/idm.example.com]
pam_gssapi_services = sudo, sudo-i

- c. Save and exit the file.
- d. Open the /etc/pam.d/sudo file for editing.
- e. Insert the following line to the top of the **#%PAM-1.0** list to allow, but not require, GSSAPI authentication for **sudo** commands:

auth sufficient pam_sss_gss.so

- f. Save and exit the file.
- 6. Restart the **SSSD** service so that the above changes take effect immediately:

\$ systemctl restart sssd

52.6. ADDITIONAL RESOURCES

• Managing remote systems in the web console

CHAPTER 53. USING RESOURCE-BASED CONSTRAINED DELEGATION IN IDM

You can use resource-based constrained delegation (RBCD) to allow access to a service. Using RBCD allows a granular control of delegation on a resource level. Access can be set by the owner of the service to which credentials are delegated. This is useful, for example, in an integration between Identity Management (IdM) and Active Directory (AD).

Since 2019, Microsoft AD enforces the use of RBCD when both target and proxy services belong to different forests.

53.1. RESOURCE-BASED CONSTRAINED DELEGATION IN IDM

RBCD allows for greater control over access delegation. This chapter covers the main differences between RBCD and general constrained delegation.

RBCD versus general constrained delegation

Resource-based constrained delegation (RBCD) differs from general constrained delegation in multiple aspects:

- Granularity: In RBCD, delegation is specified at the resource level.
- Access granting responsibility: in RBCD, access is controlled by the service owner rather than by the Kerberos administrator.

In general constrained delegation, the Service for User to Proxy (**S4U2proxy**) extension obtains a service ticket for another service on behalf of a user. The second service is typically a proxy performing work on behalf of the first service, under the authorization context of the user. Using constrained delegation eliminates the need for the user to delegate their full ticket-granting ticket (TGT).

How IdM uses constrained delegation

Identity Management (IdM) traditionally uses the Kerberos **S4U2proxy** feature to allow the web server framework to obtain an LDAP service ticket on a user's behalf.

When IdM integrates with Active Directory (AD), the IdM framework also uses constrained delegation to operate on behalf of a user towards various services, including SMB and DCE RPC end-points on both the IdM and AD sides.

How IdM can use RBCD

When an application in an IdM domain operates on behalf of users against a different service, it requires a delegation permission. In general constrained delegation, this requires the domain administrator to explicitly create a rule to allow a first service to delegate user credentials to the next service. Using RBCD, the delegation permission can be created by the owner of the service to which the credentials are delegated.

For IdM-AD integration, when both services are part of the same IdM domain, the RBCD permission can be granted on the IdM side.

IMPORTANT

Currently, only services in the IdM domain can be configured with RBCD rules. If the target service is part of an AD domain, the permission can only be granted on the AD side. As AD domain controllers cannot resolve IdM service information to create the rule, this is not currently supported.

53.2. USING RBCD TO DELEGATE ACCESS TO A SERVICE

To use RBCD to delegate access to a service, add a rule on the host where the service is running. This example procedure describes how to delegate user credentials to a file server **nfs/client.example.test** for a web application with a Kerberos service **HTTP/client.example.test**. You can do this on the **client.example.test** host, because a host always manages services running on itself.

Prerequisites

- You have access to the /etc/krb5.keytab file of the client.example.test host.
- A **nfs/client.example.test** service keytab exists.
- A keytab /path/to/web-service.keytab for HTTP/client.example.test exists.

Procedure

1. On the **client.example.test** host, obtain a Kerberos ticket:

kinit -k

2. Define the RBCD ACL:

Verification

To verify that the delegation is set up correctly, you can simulate a **testuser** user logging in through the **HTTP** service and performing a protocol transition to the **NFS** service.

1. View the NFS service to verify that the delegation rule is present:

ipa service-show nfs/client.example.test

Principal name: nfs/client.example.test@EXAMPLE.TEST Principal alias: nfs/client.example.test@EXAMPLE.TEST

Delegation principal: HTTP/client.example.test@EXAMPLE.TEST

Kevtab: True

Managed by: client.example.test

2. Obtain a Kerberos ticket for the HTTP service principal:

kinit -kt http.keytab HTTP/client.example.test

3. Verify that the ticket granting ticket is present:

klist -f

Ticket cache: KCM:0:99799

Default principal: HTTP/client.example.test@EXAMPLE.TEST

Valid starting Expires Service principal

10/13/2023 14:39:23 10/14/2023 14:05:07 krbtgt/EXAMPLE.TEST@EXAMPLE.TEST

Flags: FIA

4. Perform a protocol transition on behalf of **testuser**:

kvno -U testuser -P nfs/client.example.test

nfs/client.example.test@EXAMPLE.TEST: kvno = 1

5. Verify that tickets obtained during protocol transition on behalf of **testuser** are present:

klist -f

Ticket cache: KCM:0:99799

Default principal: HTTP/client.example.test@EXAMPLE.TEST

Valid starting Expires Service principal

10/13/2023 14:39:38 10/14/2023 14:05:07 HTTP/client.example.test@EXAMPLE.TEST

for client testuser@EXAMPLE.TEST, Flags: FAT

10/13/2023 14:39:23 10/14/2023 14:05:07 krbtgt/EXAMPLE.TEST@EXAMPLE.TEST

Flags: FIA

10/13/2023 14:39:38 10/14/2023 14:05:07 nfs/client.example.test@EXAMPLE.TEST

for client testuser@EXAMPLE.TEST, Flags: FAT
